Fatty Kidney: A Meaningful Diagnosis?

Sri Vibhavari Guntupalli, W. Charles O'Neill. *Emory University School of Medicine, Atlanta, GA.*

Background: Fatty kidney has been proposed as a detrimental metabolic condition akin to fatty liver, related to obesity and metabolic syndrome. It has primarily been recognized as an increase in fat within the renal sinus which purportedly exacerbates hypertension and CKD. Whether this condition truly exists and can be diagnosed based on

the amount of sinus fat remains unclear because the parameters that normally determine the amount of sinus fat are unknown. This was explored retrospectively in patients who underwent renal sonography in an outpatient nephrology clinic.

Methods: 137 sonograms performed in an outpatient nephrology clinic over a 5 month period were reviewed. Kidneys with cysts or hydronephrosis or that were inadequately visualized were excluded Both kidneys were excluded in 49 studies and one kidney was excluded in 20. Total kidney and sinus fat volumes were estimated by measuring areas on longitudinal images using Image J software. Data are presented as means, standard errors, and ranges.

Results: Patient age was 59 ± 2 (39-89), weight 84 ± 2.3 kg (37-142), height 67 ± 0.5 in (59-76), eGFR 46 ± 2 ml/min/1.73 m^2 (5-70), and body mass index (BMI) 29 ± 0.7 kg/m^2 (12-45). Diabetes was present in 44%, and 77% had hypertension. Sinus fat area per kidney was 13 ± 0.6 cm^2 (4-34), kidney area was 40 ± 1.1 cm^2, and ratio of sinus fat to total kidney area was 0.33 ± 0.01 (0.10-0.53). Sinus fat was strongly correlated with total kidney area (r=0.86), weakly with age (r=0.22), height (r=0.40), weight (r=0.44), BMI (r=0.29), serum triglycerides (r=0.24, and high density lipoprotein (r=0.33), but not with diabetes (p=0.30), hypertension (p=0.77), fasting blood sugar (r=0.14), hemoglobin A1C (r=0.12) or eGFR (r=0.07). After normalization to kidney size to provide a measure of excess sinus fat, only age remained as a significant determinant (r=0.45). In a multivariate model including age, diabetes, triglycerides, HDL, and BMI, only age was a significant determinant (p=0.003).

Conclusions: In this cohort comprising mostly patients with CKD, the amount of sinus fat was determined almost entirely by kidney size and did not correlate with the degree of CKD or with any metabolic parameters after adjustment for kidney size. Correlations with sinus fat volume previously reported are likely explained by the renal enlargement that occurs with obesity or hyperglycemia.

Monocyte to High-Density Lipoprotein Cholesterol Ratio (MHR) and Carotid Intima-Media Thickness (cIMT) in Patients with CKD: Secondary Analysis of Pooled Clinical Study Data

Ester Oh,[1] Zhiying You,[1] Anna Jovanovich,[1,2] Kristen L. Nowak.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]VA Eastern Colorado Health Care System, Aurora, CO.*

Background: Monocyte to high-density lipoprotein cholesterol ratio (MHR) is an emerging prognostic marker of cardiovascular diseases, including atherosclerosis. Circulating monocytes contribute to plaque development, whereas, high-density lipoprotein (HDL) cholesterol neutralizes the pro-inflammatory and pro-oxidative properties of monocytes, resulting in an atheroprotective effect. Indeed, in the general population, MHR is associated with carotid intima-media thickness (cIMT; a measure of subclinical atherosclerosis). However, this association has not been assessed in a cohort with chronic kidney disease (CKD), a population with atherosclerotic risk. The current study aimed to examine whether MHR is associated with cIMT in patients with stage 3-4 CKD.

Methods: This pooled analysis included baseline data from four clinical studies (2 published [PMID: 27647856; 36636757] and 2 unpublished [NCT Number: NCT04911491; NCT05471518]) that measured monocyte number, serum HDL cholesterol levels, and cIMT in patients with stage 3-4 CKD. Univariate and multivariate regression models were used to evaluate associations of MHR with cIMT and to further adjust for clinically relevant covariates.

Results: A total of 59 participants (39% female; 76% white; mean±SD age 65±10 years; eGFR 41±13 mL/min/1.73m^2; MHR 14±7; cIMT 0.73±0.26 mm) were included. There was an association between MHR and cIMT (β=0.286; P=0.03) in the unadjusted model (Figure). The association between MHR and cIMT was slightly attenuated after fully adjusting for age, sex, body mass index, and low-density lipoprotein cholesterol (β=0.266; P=0.06).

Conclusions: MHR may be associated with cIMT in patients with CKD; this observation should be explored further in a larger cohort.

Concordance Between Laboratory- and ICD-10 Code-Defined Stages of CKD Among Patients Hospitalized with Heart Failure in a Large US Integrated Health System

Craig Granowitz,[1] Hsin-Fang Li,[2] Shihting Chiu,[2] Deanna Rider,[3] Phil Tseng,[4] James Mudd,[3] Joshua D. Remick,[3] Slaven Sikirica,[1] Amy K. Carroll,[1] Mario Enrico Canonico,[5] Judith Hsia,[5] Marc P. Bonaca,[5] Ty Gluckman.[3] *[1]Lexicon Pharmaceuticals Inc, The Woodlands, TX; [2]Providence Heart Institute, Center for Cardiovascular Analytics, Research and Data Science, Portland, OR; [3]Providence St Joseph Health, Renton, WA; [4]Banner University Medical Center Tucson, Tucson, AZ; [5]University of Colorado, Denver, CO.*

Background: The presence of chronic kidney disease (CKD) in patients with heart failure (HF) conveys increased cardiovascular risk, while informing use of some forms of guideline-directed medical therapy. Accordingly, we sought to better understand the level of concordance between laboratory-and ICD-10 code-defined stages of non-dialysis-dependent CKD in this population.

Methods: We performed a retrospective cross-sectional analysis of patients admitted to a large integrated health system within the western US between January 1, 2018 and October 1, 2022 with a principal diagnosis of HF (defined by ICD-10 codes: I50.2, systolic heart failure; I50.3, diastolic heart failure; I50.4, combined systolic and diastolic heart failure; I11.0, hypertensive heart disease with heart failure; and I13.0 and I13.2, hypertensive heart disease with heart failure and CKD). CKD was assessed using pre-discharge laboratory data (based on the 2021 CKD-EPI equation) as well as ICD-10 codes.

Results: Over nearly 5 years, 61,238 HF hospitalizations occurred, involving 43,234 patients, with 94% having a serum creatinine available. Stage 3a, 3b, 4, and 5 CKD was noted in 21%, 22%, 17%, and 11% of hospitalized patients, respectively, based on laboratory data (Table). Among patients with an ICD-10 code for stage 3-5 CKD, rates of concordance with laboratory-defined CKD rose from 6% to 80% (Table and Figure) as renal function worsened.

Conclusions: Concordance between laboratory- and ICD-10 code defined stages of CKD rose as CKD severity increased.

Association Between Longitudinal eGFR and Sudden Cardiac Death Among CKD Patients

Jean Delannoy,[1,2] Anne-Laure Faucon,[1,3] Marie Metzger,[1] Sophie Liabeuf,[4,6] Ziad Massy,[1,5] Nicolas Mansencal,[5] Benedicte Stengel,[1] Natalia Alencar de Pinho.[1] *[1]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [2]Centre Hospitalier Universitaire de Lille, Lille, France; [3]Centre Hospitalier Sud Francilien, Corbeil-Essonnes, France; [4]Universite de Picardie Jules Verne, Amiens, France; [5]Hopital Ambroise-Pare, Boulogne-Billancourt, France; [6]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France.*

Background: The risk of sudden cardiac death (SCD) is high among dialysis dependent patients, but is poorly characterized in earlier chronic kidney disease (CKD) stages. We aimed at analyzing the relation between longitudinal eGFR and the risk of SCD in patients with moderate to severe CKD.

Methods: We analyzed data from the CKD-REIN cohort study, which enrolled adult patients with CKD stage 3 to 5 from 40 nationally representative outpatient nephrology clinics in France. All cardiovascular (CV) deaths were reviewed, and causes were adjudicated by two cardiologists. Crude and adjusted hazard ratios (HR) and 95% confidence intervals (CI) of SCD and other CV deaths associated with current eGFR value and slope were estimated with shared frailty joint models. Non-CV death and kidney replacement therapy were competing events. Models were adjusted for age, gender, urine albumin-creatinine ratio, diabetes, systolic blood pressure, body mass index, smoking, alcohol consumption and education.

Results: We included 3020 patients: 65% men, mean age 67±13 years, eGFR 34±13 mL/min/1.73m2, 30% with history of heart failure or coronary heart disease. Over a median follow-up of 5 years (interquartile range 4.6-5.2), patients underwent 12 (8-17) eGFR measurements, and the mean eGFR slope was -2 mL/min/1.73m2/year. Forty-four SCD and 102 CV deaths from other causes occurred; incidence rates were 3.7 (95% CI 2.7-5.0) and 8.7 (7.1-10.6) per 1000 person-years, respectively. Lower current eGFR value was similarly associated with the risks of SCD and other CV deaths (40 to 60% higher event hazard per 10mL/min/1.73m2 eGFR decrease, with overlapping 95% CI), whereas current eGFR slope was only associated with the risk of other CV deaths (Table).

Conclusions: Patients with more advanced CKD had higher risks of both SCD and CV deaths from other causes, but steeper eGFR decline seemed more closely related with CV deaths other than SCD.

The Relationship Between Smoking Cessation and Atherosclerotic Cardiovascular Disease Development Among Patients with CKD

Young Su Joo,[1,2] Hee Byung Koh,[1,2] Jung Tak Park,[1,2] Tae-Hyun Yoo,[1,2] Kook-Hwan Oh,[3] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1,2] *[1]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Previous studies evidenced that smoking is associated with higher atherosclerotic cardiovascular disease (ASCVD) and mortality risk. However, whether quitting smoking is associated with reduced ASCVD risk compared to maintaining smoking in patients with chronic kidney disease (CKD) is unclear. Here we evaluated the association between smoking cessation and ASCVD in patients with CKD.

Methods: We analyzed 1698 participants with non-dialysis dependent CKD from the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD). Key exclusion criteria were 1) kidney failure requiring renal replacement therapy, 2) history of ASCVD at enrollment, and 3) missing data for smoking history. We categorized participants according to smoking history and compared the risk of ASCVD and all-cause mortality. The ASCVD event was defined as a composite of myocardial infarction, stroke, or cardiovascular mortality.

Results: During 12,168 person-years of follow-up (median 8.0 years), the ASCVD event occurred in 52 (3.06%) participants, and 111 (6.26%) participants died among the KNOW-CKD participants. There were 19 (2.03%), 18 (4.09%), and 15 (4.64%) ASCVD events in never (n=935), former (n=440), and current smokers (n=323), respectively. The incidence of ASCVD was higher in current smokers (6.6 per 1000 person-years) than in former (5.7 per 1000 person-years) and never-smokers (2.8 per 1000 person-years) (P=0.02). A multivariable Cox regression showed that continuing smoking is significantly associated with ASCVD even after adjustment of age, sex, diabetes mellitus, estimated glomerular filtration ratio, and proteinuria. However, the risk of ASCVD events in former smokers was comparable to never smokers (Hazard ratio, 1.83; 95% confidence interval, 0.95-3.52).

Conclusions: In the present analysis, quitting smoking was associated with reduced risk for ASCVD compared to continuing smoking in CKD patients.

SA-PO1121

Association Between CKD and Venous Thromboembolism Post-Hospitalization

Zhong Zheng,[1] Krutika Pandit,[1] Alexander R. Chang,[2] Jung-Im Shin,[3] David M. Charytan,[1] Morgan Grams,[1] Aditya L. Surapaneni.[1] *[1]NYU Langone Health, New York, NY; [2]Geisinger Health, Danville, PA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Chronic kidney disease (CKD) has been implicated as a risk factor for venous thromboembolism (VTE), but the evidence is limited to relatively healthy populations. The objective of the current study is to discern whether parameters of kidney function and damage are associated with the occurrence of VTE after hospitalization.

Methods: We conducted a retrospective study including 24,048 and 11,737 adult individuals hospitalized within Geisinger Health and NYU Langone Health from 2004 to 2019 and 2012 to 2022, respectively. A Poisson model was used to evaluate adjusted incidence rates of post-hospitalization VTE according to estimated glomerular filtration rate (eGFR) and albuminuria stages of CKD in each cohort. Cox proportional hazards models were used to analyze associations of eGFR and urine albumin to creatinine ratio (ACR) with VTE.

Results: In the Geisinger cohort, the incidence of VTE after hospital discharge increased from 10.7 (95% CI 9.2 – 12.6) events per 1000 person-years in individuals in G1A1 (eGFR>90 mL/min/1.73 m^2 and ACR <30 mg/g) to 27.7 (95% CI 20.7 – 37.3) events per 1000 person-years in individuals with G4-5A3 (eGFR<30 mL/min/1.73 m^2 and ACR >300 mg/g), with similar findings in the NYU cohort. Meta-analysis of the two cohorts showed that every 10 mL/min/1.73m^2 reduction in eGFR below 60 mL/min/1.73m^2 and each two-fold increase in ACR were associated with a higher risk of VTE (HR 1.08, 95% CI [1.02 – 1.15] and HR 1.05, 95% CI [1.03 - 1.08]) respectively.

Conclusions: Both eGFR and ACR are independently associated with increased risk of VTE after hospitalization. The incidence rate increases with the severity of CKD. This suggests the potential need for targeted strategies of VTE prophylaxis after hospitalization in individuals with CKD.

Funding: Other NIH Support - K24HL155861 and R01DK115534

Longitudinal Trajectory Triglyceride-Glucose (TyG) Index Associated with Adverse Renal Outcome in Metabolic Dysfunction-Associated Fatty Liver Disease

Janghee Cho,[1,2] Chae Won Kim,[1,2] Hyo Jeong Kim,[1,2] Jong Hyun Jhee,[1,2] Hyeong cheon Park,[1,2] Hoon Young Choi.[1,2] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Nonalcoholic fatty liver disease (NAFLD) is considered a multisystem disease that is significantly associated with an increased risk of chronic kidney disease (CKD), cardiovascular disease and extrahepatic malignancies. Recent study demonstrated that the metabolic dysfunction-associated fatty liver disease (MAFLD) definition identified a higher proportion of individuals at risk of developing incident CKD than the NAFLD definition. Triglyceride-glucose (TyG) index is a marker for predicting metabolic syndrome and also shows an insulin resistance state. This study aimed to evaluate the association between the longitudinal trajectory TyG index and CKD progression in patients with MAFLD.

Methods: In the data from the medical records database in Gangnam Severance Hospital from 2006 through 2020, a longitudinal analysis included participants with CKD. MAFLD was diagnosed in patients with was diagnosed in individuals with hepatic steatosis and at least one of the conditions as follows: 1) overweight or obese (defined as body mass index [BMI] ≥ 23 kg/m2), 2) type 2 diabetes mellitus, or 3) two or more

metabolic abnormalities. Adverse renal outcome was defined by a reduction in the estimated glomerular filtrations rate (eGFR) ≥30% of baseline. The changing trend of TyG index over time was classified using latent variable mixture modeling with TyG index during the exposure period. Logistic regression analyses were used to determine the association between TyG index and progression of CKD by adjusting for the influence of confounders.

Results: The study included 4,286 patients, of whom 1287 had MAFLD. Mean age was 52.3 ± 10.9 years. Two distinct groups of TyG index trajectories were identified during the exposure period: decreasing (n= 649) and increasing (n=638). During the event accrual period, 136 patients (10.57 %) developed adverse renal outcomes, and the risk was higher in the increasing TyG trajectory group than in the decreasing TyG trajectory group (hazard ratio 2.265, 95% CI (1.114-4.608), P=0.024). The results were similar after adjustment for baseline clinical characteristics, comorbidities, anthropometric and laboratory findings, and eGFR.

Conclusions: An increasing tendency of TyG index was associated with a higher risk of adverse renal outcomes in patient with MAFLD.

SA-PO1123

Exploratory Study on Renal Dysfunction and Its Risk Factors in Patients with Inflammatory Bowel Disease

Akira Fujiwara, Aiko Haruna, Rina Kawano, Tatsuya Haze, Shota Suzuki, Nobuhito Hirawa. *Yokohama Shiritsu Daigaku Fuzoku Shimin Sogo Iryo Center, Yokohama, Japan.*

Background: Many studies have consistently demonstrated a higher incidence of renal function decline and progression to chronic kidney disease in patients with inflammatory bowel disease (IBD), primarily attributed to factors such as dehydration, malnutrition, medication side effects, and the impact of the underlying inflammatory bowel disease. However, there is a scarcity of data regarding the precise association between IBD and impaired renal function, as well as the specific risk factors involved. This study aims to investigate the frequency of renal function decline and identify the associated risk factors among patients diagnosed with IBD.

Methods: We performed a retrospective observational cohort study of patients at Yokohama City University Medical Center in Japan. We enrolled patients diagnosed with ulcerative colitis (UC) and Crohn's disease (CD) between 2016 and 2021 who had an eGFR of 60mL/min/1.73m^2 or higher at the time of diagnosis. We collected data, including eGFR and other blood test results, from patients over a period of two years. The participants were divided into two groups: a group that experienced a decline of 30% or more compared to baseline eGFR, and a group that did not experience a decline based on eGFR two years later. The study then evaluated the differences in baseline values between these two groups. Risk factors for renal dysfunction were assessed by univariate and multivariate analysis.

Results: A total of 351 eligible patients with UC and 184 with CD were included. The mean age at the time of diagnosis was 41.9 years with UC and 36.1 years with CD. The frequency of eGFR decline of 30% or more was 19.0% (67 patients) with UC and 17.3% (32 patients) with CD. Univariable analysis demonstrated several possible risk factors, including albumin with UC and hemoglobin with CD at the time of diagnosis. Multivariate regression analysis demonstrated albumin was an independent determinant factor with UC (95% confidence interval(CI): 0.22-0.60, *P*<0.01) and hemoglobin was an independent determinant factor with CD (95% CI: 0.53-0.87, *P*<0.01).

Conclusions: Patients with IBD have a high incidence of concurrent renal impairment, as previously reported, and in UC, albumin levels at diagnosis and in CD, hemoglobin levels at diagnosis were found to be significantly associated with decreased renal function at 2 years.

SA-PO1124

Fibrotic Burden in Patients with Hepatitis B Virus-Related Cirrhosis Is Independently Associated with Poorer Kidney Outcomes

Chan-Young Jung,[1] Hui-Yun Jung,[2] Beom Seok Kim.[2] *[1]Asan Medical Center, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Liver cirrhosis and chronic kidney disease (CKD) are chronic conditions that share cardiometabolic risk factors and pathogenic mechanisms. We investigated whether higher fibrotic burden was independently associated with poorer kidney outcomes in patients with hepatitis B virus (HBV)-related cirrhosis.

Methods: A total of 1,691 patients with HBV-related cirrhosis without baseline CKD who underwent transient elastography (TE) between March 2012 and August 2018 were selected. The study outcome was the composite of development of incident CKD, defined as the occurrence of estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2 or proteinuria (≥1+ on dipstick) on two consecutive measurements during follow-up, 50% decline in eGFR or onset of end-stage kidney disease, or all-cause mortality.

Results: The mean age was 53.4 years and 1,030 (60.9%) patients were male. During 8,379 person-years of follow-up (median 5.2 years), 60 (3.5%) patients experienced study outcomes. When stratified according to TE-defined fibrotic burden, multivariable Cox models revealed that risk of poorer kidney outcomes was 2.77-fold (95% CI, 1.16-6.63, *P*<0.001) higher in patients with cirrhotic range liver stiffness (≥11.7 kPa), compared to those without significant liver fibrosis (<7.9 kPa).

Conclusions: Higher fibrotic burden assessed using TE was independently associated with poorer kidney outcomes in patients with HBV-related cirrhosis.

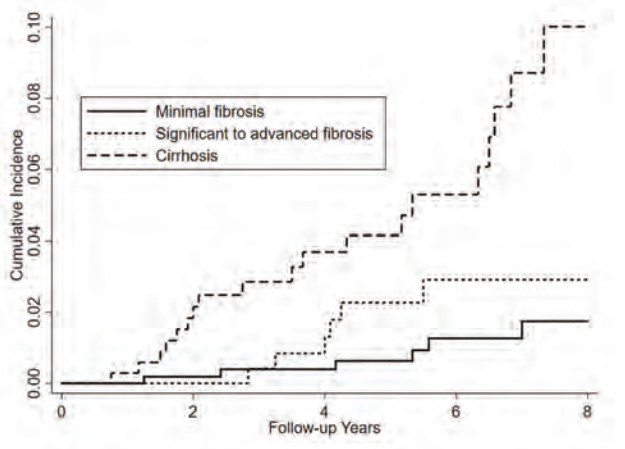

Figure 1. Cumulative incidence of adverse kidney events by fibrotic burden. Log-rank test *P* < 0.001. *Abbreviations:* TE, transient elastography.

SA-PO1125

Risk of Incident CKD Among Patients with Urolithiasis: A Nationwide Longitudinal Cohort Study

Kyoung Sook Park, Jae Young Kim. *National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Urolithiasis has been infrequently implicated to have a causal association with chronic kidney disease (CKD). Recently, several studies have demonstrated the relationship between urolithiasis and CKD. However, the generalizability of their results is limited. We aimed to examine the association between the long-term effects of urolithiasis and the risk of incident CKD.

Methods: From the longitudinal National Health Insurance Service data, this nationwide population-based cohort study identified 219,570 Korean adults with incident urolithiasis requiring procedural interventions and without prior kidney disease and 219,570 controls without urolithiasis matched by age and sex. The primary outcome of interest was the de novo development of CKD, defined as an estimated glomerular filtration rate <60 mL/min/1.73 m^2 for at least two consecutive measurements at least 90 days apart. In the sensitivity analyses, the risk of incident CKD was further examined using the outcome defined by the newly occurring diagnostic codes indicating CKD.

Results: Over a mean follow-up of 6.0 years, 12,338 (2.8%) primary outcome events of CKD were observed, with an incidence rate of 4.6 per 1,000 person-years. Multivariable Cox analysis revealed that patients with urolithiasis were associated with a higher risk of incident CKD compared with controls, with an adjusted hazard ratio of 1.41 (95% confidence interval, 1.36–1.46). This association remained consistent across all clinically relevant subgroups and when the CKD outcome was defined based on the diagnostic codes in the sensitivity analysis.

Conclusions: In this large national cohort study, patients with urolithiasis were associated with a higher risk of incident CKD than those without urolithiasis. Further studies are warranted to establish the benefits of preventing urolithiasis in reducing CKD development.

SA-PO1126

The Association of Kidney Function with Disposition After Inpatient Noncardiac Surgery: A Population-Based Cohort Study

Tyrone Harrison,[1] Tayler D. Scory,[1] Michelle M. Graham,[2] Brenda Hemmelgarn,[2] Matthew T. James,[1] Paul E. Ronksley.[1] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: People with advanced kidney disease have more non-cardiac surgeries compared to the general population and a higher risk of postoperative cardiac events and death. However, whether post-operative length of hospitalization and discharge disposition vary with kidney function is not known. In this population-based cohort study from Alberta, Canada, we explored differences in postoperative length of stay (LOS), the number of days spent at home after surgery within 30 days (home time), and the discharge disposition according to preoperative kidney function.

Methods: We identified adults undergoing inpatient surgery between April 2005 and February 2019, and categorized them by preoperative outpatient kidney function based on eGFR in mL/min/1.73m^2: ≥ 60 (G1-2), 45-59 (G3a), 30-44 (G3b), 15-29 (G4), < 15 not receiving dialysis (G5ND) and receiving dialysis (G5D), and kidney transplant recipients (G1T-5T). Outcomes of interest were LOS, home time, and discharge disposition. We estimated associations between eGFR category and outcomes with multivariable generalized estimating equation (GEE) models to account for multiple surgeries clustered at the patient level.

Results: We identified 927,560 inpatient surgeries in 666,770 people, with 55.9% of patients being female and median age of 57.4 years. People receiving dialysis (G5D) had the longest adjusted LOS at 17.9 days (95%CI 17.0, 18.7), more than 2 times greater

than people with G1-2 kidney function (Adjusted Rate Ratio [ARR] of 2.21 [95%CI 2.10, 2.32]). This group also had the lowest home time, with an ARR of 0.69 (95%CI 0.67, 0.70) compared to people with G1-2 function. Most people were discharged home without support after surgery (82.8%), though people with G5D function were discharged to a facility with 24-hour nursing care nearly 4 times more often than the G1-2 group. There were graded increases in risks of these outcomes among adults with G3-G5ND kidney function.

Conclusions: Patients with advanced kidney disease spend significantly more time in hospital after surgery, and less time at home. They are also more likely to be discharged with additional support at home or to a facility with nursing support. These findings may help inform perioperative resource planning and shared-decision making.

Association of Albuminuria with Interstitial Lung Abnormalities

Faeq Husain-Syed,[1,2] Indika V. Mallawaarachchi,[1] Jennie Z. Ma,[1] Catherine Debban,[1] Eric A. Hoffman,[3] Claire McGroder,[4] Michaela R. Anderson,[5] Ganesh Raghu,[6] Steven Kawut,[5] Anna J. Podolanczuk,[7] Ani W. Manichaikul,[1] Stephen R. Rich,[1] Christine Kim Garcia,[4] Elizabeth C. Oelsner,[4] Julia J. Scialla,[1] R. Graham Barr,[4] John Kim.[1,4] *[1]University of Virginia, Charlottesville, VA; [2]Justus Liebig Universitat Giessen, Giessen, Germany; [3]University of Iowa Hospitals and Clinics, Iowa City, IA; [4]Columbia University Irving Medical Center, New York, NY; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]University of Washington, Seattle, WA; [7]Weill Cornell Medicine, New York, NY.*

Background: Pulmonary microvascular dysfunction has been implicated in the pathogenesis of pulmonary fibrosis. Albuminuria, a marker of endothelial dysfunction, may be a risk factor in the early development of interstitial lung disease (ILD). We hypothesized that higher UACR would be associated with interstitial lung abnormalities (ILA), which may represent early stages of pulmonary fibrosis.

Methods: A subset of the U.S. population-based Multi-Ethnic Study of Atherosclerosis cohort (n = 2,260) had spot UACR and full-lung CT measurements at Exam 5 (2010–2012). The association between UACR and ILA was examined cross-sectionally using a generalized linear mixed model accounting for clustering by study site. Due to potential differential associations by age, we performed a stratified analysis with an age cutoff of 65 years. Kaplan-Meier estimation was used to examine whether UACR modified the association of ILA with all-cause mortality (2010–2019).

Results: Compared to participants without ILA, those with ILA (11.8%) were older (74.2±9.1 vs. 68.2±9.0 years), had higher UACR levels (8.4 [IQR, 4.0–20.3] vs. 5.8 [3.5–12.6] mg/g creatinine), and a higher prevalence of smoking history. After adjustment for covariates, UACR was not associated with ILA in the overall group (P=0.71). An association was observed in the age≥65 (OR=1.17, 95% CI: 1.06–1.29; P=0.002) but not in the age<65 group (P=0.88). Adjustment for age in stratified analysis did not change the estimates considerably. The presence of both ILA and higher UACR (≥10 mg/g) was associated with greater risk of death when compared with fulfilling only one or none of the two criteria (Figure; log-rank P<0.001).

Conclusions: Albuminuria was associated with more ILA and worse survival in older community-dwelling adults. Albuminuria may be a risk factor in early ILD and requires further investigation.

Impact of CKD on Incidence of Visual Impairment: The Singapore Epidemiology of Eye Diseases Study

Charumathi Sabanayagam,[1,2] Joanna Chiok,[1] Feng He,[1] Cynthia C. Lim,[3] Gavin Tan,[1,2] Ching-Yu Cheng.[1,2] *[1]Singapore Eye Research Institute, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Singapore General Hospital, Singapore, Singapore.*

Background: To examine the impact of chronic kidney disease (CKD) on the incidence and severity of visual impairment (VI) in a population-based sample of Asian adults.

Methods: We analysed data from 4732 Chinese, Malay and Indian adults who participated in the baseline (2004-2011, aged 40-80 years) and 6-year (2011-2017) follow-up visit of the Singapore Epidemiology of Eye Diseases and were free of VI at baseline. CKD (n=447, 9.4%) was defined as an estimated glomerular filtration rate (eGFR)<60 ml/min/1.73 m2 and severity of CKD was categorized into stages G1-5. Participants underwent comprehensive eye examinations including refraction and slit-lamp examinations. Incident VI was defined as best-corrected visual acuity (BCVA) <20/40 in the better eye. Severity of VI was defined as normal, low vision and blindness (≥20/40, <20/40 to >20/200 and ≤20/200). Associations between CKD and VI were examined using Logistic regression models adjusted for age, gender, ethnicity, diabetes, and hypertension status.

Results: The incidence of VI was significantly higher in individuals with CKD compared to those without (14.3% vs. 3.3%, p<0.001). In severity analyses, incidence of low vision and blindness were also higher in those with CKD (13.4% and 0.9%) compared to those without (3.3% and 0%, p<0.001). There was a clear trend of increasing incidence of VI with the progression of CKD stages, with rates of 3.3%, 13.5%, and 16.3% in stage G1-2, G3a, and G3b-G5 (p-trend <0.001, Figure 1). After adjusting for other factors, CKD was independently associated with an increased risk of any VI, with an odds ratio of 1.47 (95% confidence interval: 1.03 -2.10).

Conclusions: Our results suggests that the presence of CKD increased the risk and severity of VI in Asian adults. Given the increasing prevalence of CKD worldwide, these findings highlight the importance of regular ocular examinations for individuals with CKD to reduce the risk of VI.

Time Is Nephron: Chronic Urinary Bladder Herniation Resulting in ESKD

Waryaam Singh,[1] Jacob Ninan.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]MultiCare Capital Medical Center, Olympia, WA.*

Introduction: Inguinal hernias involving the urinary bladder occur in 0.4-3% of cases. They are often asymptomatic but can result in lower abdominal discomfort, urinary tract infections, and kidney complications. We present a patient with an inguinal urinary bladder hernia presenting with end-stage kidney disease.

Case Description: 43-year-old class 3 obese male was admitted for an enlarging right inguinal hernia. The surgeon advised him to return to the specialty clinic for his 8 month-long-lump after seeking urological assistance and deciding on his choice of surgical option offered. 3 weeks before admission, he was noted to be uremic and oliguric. On admission, his vital signs were stable, and physical examination revealed bilateral inguinal hernia, and lab results showed S. Cr 14.07mg/dL, BUN 226mg/dL, S. K 6.1mmol/L, and S. Bicarb 7mmol/L. The CT scan revealed a grossly distended urinary bladder herniating into the right inguinal canal and bilateral hydronephrosis. The patient declined kidney replacement therapy due to concerns about his quality of life. He was managed medically and discharged home on hospice care at his request. His S. Cr levels stabilized(in the high 7s), and he passed away one month after hospitalization.

Discussion: Urinary bladder herniation(UBH) can occur as direct inguinal hernia and, less commonly, as indirect inguinal or femoral hernia. Male gender, advanced age, obesity, bladder obstruction, and abdominal wall weakness are contributing factors. Most cases are asymptomatic, but some experience groin pain, urinary retention, hematuria, flank pain, or lower urinary tract symptoms. If left untreated, long-standing urinary bladder hernias cause renal failure, bladder perforation, recurrent stones, or hydronephrosis.

Symptomatic UBH usually require emergency management, initial drainage using a Foley catheter before definitive surgery. Ultrasound, computed tomography scan, or MRI can aid in diagnosis and surgical planning. Open repair of urinary bladder herniation involving reduction of the bladder, followed by a standard herniorrhaphy technique, is the typical approach; however, conventional and robotic-assisted laparoscopic repairs have also been reported. UBH is a rare and overlooked condition more prevalent in high-risk populations such as overweight men. Timely diagnosis and surgical repair are crucial to prevent irreversible kidney damage and fatal outcomes.

SA-PO1130

Dynamic Bayesian Networks (DBN) Predicted ≥40% Decline in eGFR over Six Years

Panayiotis Petousis,[1] David Gordon,[1] Kenn B. Daratha,[2] Keith C. Norris,[1] Katherine R. Tuttle,[2] Susanne B. Nicholas,[1] Alex Bui.[1] Center for Kidney Disease Research, Education, and Hope (CURE-CKD). *[1]University of California Los Angeles, Los Angeles, CA; [2]Providence Medical Research Center, Spokane, WA.*

Background: A ≥40% decline in eGFR over two years is associated with an adjusted hazard ratio of ~10 for progression to kidney failure in patients with chronic kidney disease (CKD). Here, we predicted ≥40% eGFR decline at least one year in advance and simulated missing values along a patient's CKD trajectory.

Methods: Electronic health records from patients with and at-risk (diabetes, prediabetes, hypertension) for CKD (by diagnosis code and eGFR <60 mL/min/1.73 m^2) from the CURE-CKD Registry (1/1/2006-12/31/2020; N=2,250,806) at Providence (N=1,917,619) and UCLA (N=333,187) Health were used. A DBN for CURE-CKD was created using the Ranking Approaches for Unknown Structures software. The DBN was trained, tuned, and validated on a blind test set. We included demographics, comorbidities, lab values, medications, and vitals over 6 years. The primary outcome was an annual ≥40% decline in eGFR from baseline.

Results: Using observations before the prediction year, the DBN predicted the outcome of the target year despite an average rate of 29% missing values across most variables. Model performance improved over time, suggesting that longer follow-up improved the simulation of missing values and the prediction of ≥40% eGFR decline. By the 6th year, the model achieved an area under the receiver operating characteristic curve (AUCROC) of 0.83 and an average precision (AP) of 0.21 (Figure). When stratified, patients with albuminuria/proteinuria had the highest prevalence of ≥40% eGFR decline and were most accurately predicted (Table), and higher performance was observed in Hispanic and Black groups, who had a higher prevalence of ≥40% eGFR decline versus the whole population.

Conclusions: DBNs can simulate missing data to predict ≥40% eGFR decline in patients with CKD and in racial and ethnic minority groups. Model performance dramatically improved with longer follow-up.

Characterization of Acid-Base Status of Critically Ill COVID-19 Patients by Stewart's Methodology

Sergio P. de Souza,[1,2] Marcelo Lopes,[1,2] Marcelo D. Silveira,[1,2] Fernanda O. Coelho,[1,2] Rogerio Passos.[1,2] *[1]Hospital Sao Rafael, Salvador, Brazil; [2]Rede D'Or Sao Luiz, Rio de Janeiro, Brazil.*

Background: SARS-CoV-2 infection is associated with unfavorable outcomes and high costs. Although the occurrence of electrolyte derangements in the affected patients is expected to have significative clinical impact, more detailed description and associations to outcomes remains scarce, and limited to the traditional approach of Hendelsson-Hasselbach.

Methods: We conducted a cohort of adult patients with ICU stay of more than 4 days that had blood gas analysis and a typical chest CT involvement at admission. SARS-COV-2 infection was diagnosed by a positive PCR from nasal swab. Data was analyzed in the PSPP statistical package, version 1.2.1.

Results: A total of 799 patients had a COVID-19 diagnosis in our hospital, and 456 were admitted to an intensive care unit. From these, 211 patients had at least a 4 day ICU hospital and were analyzed; the mortality rate of this group was 13,7%. Overall, 149 patients (70,6%) presented alkalemia, 28 acidemia (13.3%) and the remaining 34 patients (16.2%) had a normal arterial pH. From those presenting acidemia, most had a low aSID (20 patients, 9,5%); within the group with alkalemia, 128 (61% of all patients) had respiratory origin. The non-survivors were older, had more co-morbidities and a higher Charlson's and SAPS 3 scores. Bacterial infections were also more common in this group. Blood gas variables were similar in both groups; overall, we did not find severe acid-base derangements in this population. Stewart 's variables analyzed - SID eff, SID app, SIG, and the albumin, lactate, phosphorus and chloride effect were not different between both groups.

Conclusions: The description of acid-base variables in SARS-COV-2 infected patients remains scarce, and limited to the traditional approach. Alkalemia was the most prevalent acid base disturbance in this population, and mainly of respiratory origin. Although we did not found association between acid-base variables by Stewart's methodology and mortality, dialysis and respiratory failure, the use of this innovative methodology may provide valuable insights in the description of this severe disease.

PUB002

COVID-19 Is Associated with Hyponatremia up to 90 Days, but Long COVID Is Not Associated with Chronic Hyponatremia

Steven Achinger,[1,2] Ambuj Kumar,[1] Athanasios Tsalatsanis.[1] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]Watson Clinic LLP, Lakeland, FL.*

Background: Hyponatremia has also been reported with high frequency (25% to 45%) and to predict mortality among patients hospitalized with COVID–19. There are no studies that address hyponatremia at longer periods after COVID - 19 diagnosis.

Methods: This is a retrospective cohort studying using data from TriNetX research network containing 93 million unique EMR records. **Exposure**: COVID-19 diagnosis. **Outcomes:** serum sodium levels, mild (130-134 mmol/L), moderate (125-129 mmol/L), or severe (<124mmol/L) hyponatremia. Differences in outcomes between the respective cases and control cohorts were evaluated after propensity score matching with student t-test for the continuous variables and chi-squared test for dichotomous variables. We report risk differences and differences in mean sodium level.

Results: In high-risk patients, COVID - 19 cases had lower sodium values up to 30 days after COVID-19 and had higher risk of hyponatremia up to 90 days following COVID-19 than the controls. In low-risk patients, COVID-19 cases had lower sodium values up to 14 days after COVID-19 and had a higher risk of mild or moderate hyponatremia up to 30 days following the COVID-19 diagnosis than the controls and higher risk of severe hyponatremia up to 7 days after COVID-19 than the controls; whereas at all greater time points, there were no differences in rates of hyponatremia between the cases and controls.

Conclusions: COVID – 19 is associated with the development of mild, moderate and severe hyponatremia that persists for durations longer the acute time frame. COVID – 19 during the sub-acute phase can be complicated by hyponatremia, but that durations > 90 days (long COVID), are not associated with hyponatremia.

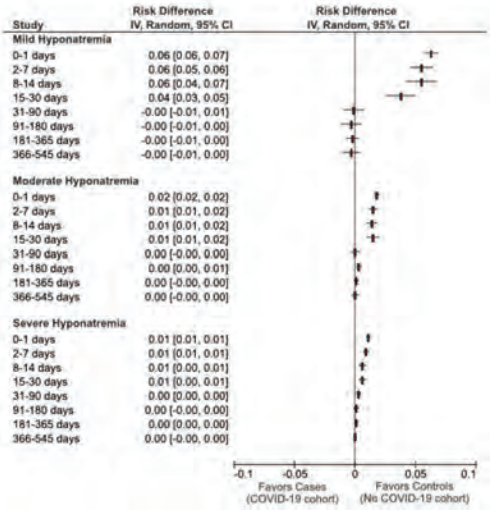

Figure 3. Low risk

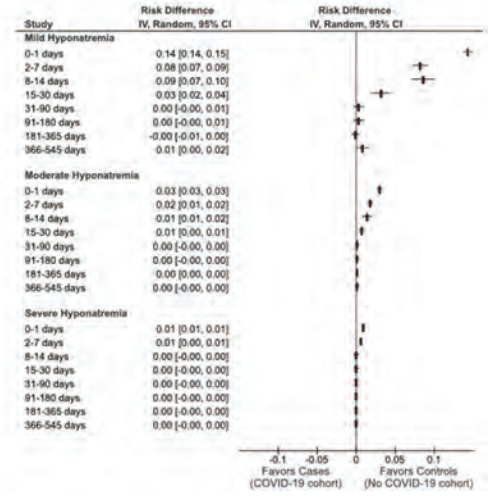

PUB003

New-Onset Severe Eosinophilic Granulomatosis with Polyangiitis (EGPA) Following the Third Dose of COVID-19 Vaccine

Samia Ait Faqih, Krishnamoorthy Sundara Raman, Alaedin Shurrab. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Vaccines against SARS-CoV-2 represent a pivotal and effective countermeasure to contain the COVID-19 pandemic by stimulating both humoral and cellular immunity. Although anti-SARS-CoV-2 vaccines are highly safe, there are reports suggesting that they might be able to trigger de-novo or exacerbate pre-existing immune-mediated diseases. This case report suggests association between COVID-19 vaccination and new-onset EGPA.

Case Description: A 53-year-old patient presented with a history of asymmetrical hand clumsiness associated with difficulty in walking. He also reported a history of fatigue, myalgia and nonpruritic skin rash over the back and both lower limbs since he received the third dose of COVID-19 vaccine. The first two doses COVID-19 vaccines were given eight months ago, three-week apart, and he was not diagnosed to have COVID-19 disease before. The neurological assessment showed distal muscle weakness of both upper limbs. Lower limb examination revealed non-blanchable violaceous skin rash over both shins. The autoimmune panel was positive for p-ANCA. Nerve Conduction study is consistent with acute mononeuritis multiplex. A skin biopsy showed leucocytoclastic vasculitis, the kidney biopsy confirmed the presence of pauci-immune necrotizing and crescentic glomerulonephritis. He received induction therapy of methylprednisolone and Rituximab with a repeated dose two weeks later. Then maintained on a tapering dose of prednisolone and Rituximab infusion every 6 months. One year later, the patient was still having left wrist drop with significant wasting of the small muscles of both hands, his renal function was stable with undetectable ANCA antibody level. Repeat EMG and NCS showed worsening electrophysiological features of mononeuritis multiplex. He has since been started on cyclophosphamide and IV Ig.

Discussion: We present a case of new-onset multisystemic EGPA following a booster dose of covid 19 vaccine in a patient with no personal or family history of auto immunity. Since there is no temporal association between vaccine administration and disease onset, it is difficult to establish a causal relationship. Nevertheless, our report may suggest that caution should be paid during the administration of Covid 19 vaccines. However, these events are extremely rare and further studies are required to draw reliable conclusions.

PUB004

A Retrospective Cohort Study on the Duration of Dexamethasone and Clinical Outcomes of CKD Patients on Dialysis with Severe to Critical COVID-19

Marie Kathleen R. Uy-Huang Chih Chang. *National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: Chronic kidney disease [CKD] is considered an important comorbidity associated with adverse outcomes in patients with COVID-19. There is no current studies on corticosteroids on dialysis patients. Hence, this study aimed to compare the clinical outcomes of patients who received a short course and a longer course. The results and analysis from this study will help treat CKD patients with severe to critical COVID-19.

Methods: A retrospective review of patients with CKD on dialysis, with a diagnosis of severe or critical COVID-19, received intravenous dexamethasone, and was admitted at the NKTI from July 1, 2020 to December 31, 2021. This study included all adult patients who, before COVID-19 infection, were diagnosed with CKD V and on dialysis and tested positive on COVID RT-PCR. Excluded are patients who had been on steroid therapy before COVID-19 infection or admitted as reinfection or readmission for COVID-19.

Results: The analysis showed no significant difference in the baseline measurements of oxygen saturation, ejection fraction, hemoglobin, WBC, platelets, inflammatory markers between groups. The median number of days of dexamethasone was 3 days and 10 days for shorter and longer course, respectively. Patients in the longer course group had lower 30-day mortality (54%). The 30-day mortality rates were 67.44 (95% CI 61.83–72.71) % overall. The numbers needed to treat to prevent 1 death was 3.33 and 3.45 among severely-ill and critically-ill COVID-19 patients, respectively. A longer dexamethasone course showed lower 30-day mortality. In addition, patients in the longer course group had a prolonged duration of confinement and days on oxygen support.

Conclusions: Our data shows that 6 mg dexamethasone for more than 5 days, with a median of 10 days, lowers the risk of death in patients with severe to critical COVID-19 with CKD Stage V on dialysis. In addition, patients' period of hospitalization and need for oxygen support was directly proportional to the duration of dexamethasone. Therefore, appropriate dosage and duration of dexamethasone after onset are essential in treating patients with severe and critical COVID-19.

PUB005

An Unusual Presentation of Acquired Thrombotic Thrombocytopenic Purpura in a Young Patient with COVID-19

Leonardo R. Ramirez Botana. *Hospital de la Concepcion, San German, Puerto Rico.*

Introduction: Acquired thrombotic thrombocytopenic purpura (aTTP) is a medical emergency. Untreated thrombotic thrombocytopenic purpura is usually fatal, but with proper treatment, survival rates are over 90 %. Cases of aTTP have been described in a population greater than 55-year-old. Very few cases after COVID- 19 infection in a population between 20 and 30 years old.

Case Description: We describe a 36-year-old man, no past medical history, who developed a progressive worsening shortness of breath during active COVID-19 infection. He had positive COVID-19 Ag test 6 days ago before admission. These symptoms were associated with moderate abdominal pain, 7/10 intensity, localized upper and left side of the abdomen, non radiated, constant, that worsening any time the patient breath. Patient has 38.6 C of temperature at ER, and after 2 hours of this episode he started to had numbness and weakness in left arm, one episode of left arm involuntary movement, fatigue and general weakness. Labs shows anemia, profound thrombocytopenia with schistocytes on peripheral smear, acute renal failure and normal coagulation profile, Direct Coombs Test negative and was order Adams13 test Antibody.

Discussion: The association of this episode of aTTP with COVID-19 infection, with no other discernible cause in this patient, made COVID-19 infection the most likely the trigger to produce this disase. Circulating SARS-CoV-2 attaches and enters into the cytoplasm of monocytes, platelets, and endothelial cells; causing their activation and release of pro-inflammatory and pro-coagulant activators leading to a hypercoagulable state. In four of six reported cases reviewed, aTTP was present at the time of the COVID-19 diagnosis or within 10 days. Four out of six COVID-19 infected patients who developed aTTP had a mild course of COVID-19 infection. All patients reported had recovered after treatment, however, three patients had a prolonged and complicated recover. This case highlights the fact that TTP may occur with days after be diagnosed of COVID-19 infection. Clinicians should be aware of this association for prompt recognition and timely treatment. There is a significant increase in acquired thrombotic thrombocytopenic purpura in patients with COVID 19 infection, however, with the correct treatment, the severity of acquired thrombotic thrombocytopenic purpura may have short-term prognostic significance.

PUB006

Prevalence and Risk factors of AKI in Hospitalized Patients with COVID-19

Reem J. Hashem, Hanaa O. Okda, Nashwa M. Elgharbwy, Kamal M. Okasha. *Tanta University, Tanta, Egypt.*

Background: Acute kidney injury (AKI) has been frequently described in Covid-19 patients with reports confirming its negative impact on Covid outcomes.

Methods: This prospective cross-sectional study focused on all admitted Covid19 patients between September and December 2020. A total of 480 patients were enrolled. Patient demographics, medical records, and laboratory data were gathered. Patients were split into two groups: AKI and non-AKI. Comparisons comprised demographics, labs, ICU transfer, need for ventilation and oxygen therapy, medications, hospital stay, and deaths. Patients COVID - 19 positive patient diagnosis based on Clinical symptoms and signs (Fever, Cough, Breathing difficulties, Organ failure). Laboratory findings as elevation of inflammatory biomarkers (CRP, Ferritin, D-dimer, INR, Lactate dehydrogenase), decrease in lymphocyte and hypokalaemia. and Polymerise chain reaction (PCR).

Results: Showed incidence rate of 40.83% of AKI. The prevalence of HTN was 57.1% in the AKI group which was statistically significantly higher as compared with the non-AKI cases, as well as the prevalence of DM was 67.3% in the AKI group which was significantly higher. Fever was the most common clinical presentation (93.3%) followed by fatigue (70.8%), cough (65.8%) and headache (60%). The prevalence of critical Covid19 disease severity was 44.9% in the AKI group which was significantly higher as compared with the non- AKI (19.7%) (p= 0.005). The duration of hospital admission was statistically significantly longer in the AKI cases. In terms of ICU transfer, 55.1% of patients with AKI were transferred to the ICU and 33.8% of the non-AKI group (P<0.001%). Regarding overall mortality11.7% died in hospital. Among AKI patients, 16.3% died compared to 8.5% among non-AKI group (P=0.008). Also severity of the disease was 44.9% in AkI group and 19.7% in non AKI patients (P=0.005).

Conclusions: Acute kidney injury in patients infected with Covid-19 is associated with a significant increase in patients' morbidity and mortality. Identification of the risk factors is crucial for early anticipation and management of this dreadful complication. This study should make risk stratification of clinical-based scoring systems for the prediction of AKI in Covid patients in order to early manage the problem in high-risk cases by protective measures.

PUB007

Analysis of Reasons for Refusing COVID Vaccination or Boosters in Central Washington Patient Populations with CKD

Sajal Kumar,[1,2] Keaton Duty,[2] Mitali Kumar.[3] *[1]Nephrology Associates of Yakima, Yakima, WA; [2]Pacific Northwest University of Health Sciences, Yakima, WA; [3]Vanderbilt University, Nashville, TN.*

Background: Numerous studies have demonstrated improved hospitalization outcomes and reduced mortality rates in COVID-vaccinated patients with CKD, including those who have received a booster. The Nephrology Associates of Yakima (NAY), located in rural Central Washington manages a diverse patient population who are on dialysis, are immunosuppressed with kidney transplants, and are diagnosed with early CKD. These patients are associated with high mortality rates with COVID infections. Despite all the public health emphasis, it is concerning that vulnerable high risk populations, such as patients with CKD, continue to exhibit vaccine hesitancy.

Methods: We screened 345 patients in central Washington area to identify individuals who either refused all COVID vaccines or refused the COVID booster after receiving the initial Covid vaccine series during the encounter period of December 2022 to March 2023. Of the 40 patients who were identified during the screening process, 36 individuals (52% women and 48% men) agreed to participate. Surveys were conducted during appointments at the NAY clinic and the 5 DaVita Dialysis Centers located in Yakima and Kittitas County. In total 4 patients refused to fill the survey.

Results: Of the total 36 pts identified, 23 patients had ESKD and were on dialysis, 2 pts had Kidney Transplant and remaining 11 had Other CKD issues. The Age spread : 6 pts were less than 40 yrs old, age group 40 to 60 yrs included 7 pts and Age group More than 60 yrs included 23 total pts. The Race/Ethnicity data : Caucasian pts total included 25, Hispanic pts total included 10, Asian pt was total only 1. Native American pts and African American pts were none in the Covid vaccine refusal group. Our Results showed 36.11% of the 36 patients indicated, "worried about new mRNA vaccine technology" as the primary reason for refusal, followed by, "worried about side effects" at 22.22%, and "unsure of vaccine effectiveness" at 16.66%. Other reasons given were "patient believes in natural immunity" at 13.88%, "patient usually does not take any vaccines" in 8.33% and "Religious reasons" in 2.77% of patients.

Conclusions: This pilot study highlights the critical need for further patient education, especially in high-risk population. We need to improve the general public's understanding of mRNA technology for better Covid vaccine acceptance.

SARS-CoV-2 Nucleocapsid Antibodies in Kidney Transplant Recipients Are Common After Reinfection

Matthew R. D'Costa, Hersharan K. Sran, Emmett Tsz Yeung Wong, Zi Yun Chang, Anantharaman Vathsala. *National University Hospital, Singapore, Singapore.*

Background: There remains limited data on SARS-COV-2 immunity after COVID-19 infection in kidney transplant recipients (KTR), and the severity of COVID-19 reinfection (RI) in KTR is uncertain.

Methods: We performed a retrospective, single-centre study of all SARS-CoV-2-infected KTR confirmed by PCR during the Delta (09/17-12/28/21) and Omicron BA.1, BA.2, BA.4, BA.5 and XBB (12/29/21-12/31/22) waves. SARS-CoV-2 spike antibody (SpAb) levels were assessed at diagnosis. RI was defined as a new infection confirmed by PCR >90 days after recovery of first infection including symptom resolution and repeat surveillance PCR cycle threshold (CT) >25. Post-infection immunity was assessed including SpAb and SARS-COV-2 nucleocapsid (NAb) antibody >42 days post-infection.

Results: In all, 276 KTR had ≥ 1 COVID-19 infection. They were a mean 53±12 years old, 52% male, 65% ethnic Chinese, 19% obese, 36% diabetic, 91% vaccinated with ≥3 mRNA SARS-COV-2 vaccines; 56% living kidney transplant, vintage 9±7 years, 9% eGFR ≤ 30 ml/min, and 87% maintained on calcineurin-inhibitor + anti-metabolite + prednisolone. RI occurred in 25 (9%) KTR at 210 (range 103-436) days after the infection – all with Omicron variants. RI had higher SpAb at diagnosis; characteristics were otherwise similar. Severe disease (supplemental oxygen, ICU stay) occurred in 22 KTR and 3 died; no KTR with RI had severe disease. Post-infection SpAb was similar but NAb were more likely to be reactive in RI (Table 1).

Conclusions: RI in KTR was relatively mild in our well-vaccinated cohort. NAb is common in KTR with RI likely due to a memory response from prior infection. More studies are needed on the longevity and efficacy of NAb on future RI in KTR.

Table 1: Humoral immunity of kidney transplant recipients after COVID-19 infection

Severe disease (supplemental O2 or worse)	1.56 (0.24-9.91)	-

1.Roche® Cobas SARS-CoV-2-S assay (Spike antibody) range: non-reactive (<0.4) to >12,5000 U/mL (upper limit of assay). Non-reactive = 0 and >12,500 = 12,500 for purposes of analysis.
2. Roche® Cobas SARS-CoV-2-N assay (Nucleocapsid antibody); reactive = cut-off value ≥1.0 U/L. 8/25 (32%) of KTR with RI had reactive nucleocapsid antibody after their first infection.
3.Monoclonal antibody (mAb) treatment – sotrovimab for Delta if SpAb <100 U/mL and Ba.1 if SpAb <250 U/mL; tixagevimab/cilgavimab for BA.2 onwards –and not on oxygen/severe disease (Supp02). Tixagevimab/cilgavimab was also given for pre-exposure was given as pre-exposure prophylaxis if no prior history of infection or post-exposure prophylaxis if exposed to a household contact with COVID-19.
4.Remdesivir was given at ≤7 days of illness for BA.2 onwards if SpAb >500.
5.Adjusting for reinfection and COVID-19 disease variant as KTR with Delta variant did not have reinfection with Delta.

PUB009

Effect of CKD on the Severity of COVID-19 in Hypertensive Subjects

Javier Nieto,[1] Maravillas Sánchez Macarro,[2] Javier Sobrino,[3] Francisco Valls-Roca,[4] Jesus Iturralde-Iriso,[5] Rafael Crespo Sabarís,[6] Fernando García Romanos,[7] Francisco Fuentes-Jimenez,[8] Alcibiades Segundo Diaz Vera,[9] Angeles Velasco Soria,[10] Manuel Angel Gómez Marcos,[11] José Abellán Alemán.[2] HTA-COVID-19 Study Group. *[1]Hospital General Universitario de Ciudad Real, Ciudad Real, Spain; [2]Universidad Catolica San Antonio de Murcia, Murcia, Spain; [3]Fundacio Hospital de l'Esperit Sant, Santa Coloma de Gramenet, Spain; [4]Sociedad Valenciana de HTA y RV, Valencia, Spain; [5]Unidad de Atención Primaria La Habana-Cuba., Vitoria, Spain; [6]Dirección Médica de Atención Primaria, Logroño, Spain; [7]Centro de Salud Santa Catalina, Palma, Spain; [8]Hospital Universitario Reina Sofia, Cordoba, Spain; [9]Centro de Salud Elizondo, Pamplona, Spain; [10]Centro de Salud San Andrés, Murcia, Spain; [11]Universidad de Salamanca, Salamanca, Spain.*

Background: Comorbidities such as hypertension (HTN) or chronic kidney disease (CKD) may worsen the prognosis of subjects infected by SARS-Cov-2 and hypertensives are at greater risk of suffering renal dysfunction. The purpose of this study is to assess the effect of CKD on the progression of COVID-19 in hypertensive patients.

Methods: Multicenter, observational, cross-sectional, retrospective and analytical study. Patients, over 18y, were selected by random sampling in 10 autonomous regions of Spain, among subjects with treated HTN, infected by SARS-Cov-2 under Primary Care Health. CKD was defined as GFR<60 mL/min/1.73m^2 and/or UACR>30 mg/g creatinine. The Pearsons test and multivariate logistic regression analysis adjusted for age, sex, smoking, and obesity were used to assess the association between the severity of COVID-19 and the presence of CKD in our hypertensive population.

Results: 1372 patients were recruited, mean age 67y, women 51%, smoking 13%, obesity 44%, diabetes 28%, controlled HTN 56% (BP<140/ 90mmHg). The severity of the progression of COVID-19 was defined as mild-asymptomatic 971 (71%), hospital admission 401 (29%), ICU admission 74 (5.4%), death 48 (rate of lethality 4%). 63% had CKD with a worse prognosis, since of total hospitalizations we found 69% with CKD vs 31% without it (p=0.0064). 18% of patients with GFR<60 (77y, 54% women) also progressed worse, with 44% hospitalizations, 8% in the ICU, and mortality11%. Comparing mild-asymptomatic subjects with hospitalizated patients, those with reduced GFR had an unfavorable course (OR=2.4; 95%CI:1.6-3.7; p<0.001), without significant differences in BP. There was also greater severity of COVID-19 in smoking patients with CKD (OR=6.8; 95%CI:2.4-19.5; p<0.001) for hospitalization and (OR=6.0; 95%CI:1.7-21.6; p<0.05) for ICU admission. We did not found any effect of RAS inhibitors, statins or antidiabetic drugs.

Conclusions: The prevalence of CKD among hipertensive subjects infected by SARS-Cov-2, in our Primare Care environment is very high. CKD, even without a reduced GFR, is related to a greater severity in the progression of COVID-19. Smoking seems to exert a deleterious modulatory effect associated to CKD for the disease outcomes.

PUB010

Detailed Analysis of Kidney Transplant Recipients Admitted to a Tertiary Care Transplant Center with SARS-CoV-2

Emily E. Zona, Mina L. Gibes, Asha S. Jain, Juan S. Danobeitia, Jacqueline Garonzik Wang, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin-Madison, Madison, WI.*

Background: Kidney transplant recipients (KTR) are a vulnerable immunocompromised population at risk of severe disease and mortality from COVID-19.

Methods: We retrospectively describe all adult KTRs who were hospitalized at our center during their first episode of COVID-19 between 04/2020 and 04/2022 and had at least 12 months follow-up (unless they experienced graft failure or death). Outcomes of interest included length of hospitalization, intensive care unit admission, respiratory symptoms at admission, uncensored graft failure at the last follow up, and death related to COVID-19.

Results: 98 KTRs were hospitalized at our center due to their first episode of COVID-19 between 04/2020 and 04/2022. The mean age at COVID-19 diagnosis was 57± 14.2 yrs. 57% of the cohort received at least one vaccine dose against SARS-CoV-2. Of those unvaccinated, 33% (14) had death at last follow-up compared to 26.7% (15) of those vaccinated. The most common cause of end stage kidney disease was diabetes mellitus (29%). The average length of hospitalization was 11.5 days, with 66% of KTRs presenting with respiratory symptoms on admission and 21% requiring intensive care unit admission. 30% died during the study period, of which 19% were COVID-19-related (Figure 1). Mortality was highest within a month of COVID-19 diagnosis.

Conclusions: In this single-center descriptive retrospective study of 98 KTRs, one fifth of those hospitalized at our center died related to COVID-19. KTRs still have high COVID-19-related morbidity and mortality.

PUB011

Trajectory of Kidney Function in Patients with AKI and COVID-19 in a Reference Center in Mexico

Jose F. Real Garcia,[1] Lilia M. Rizo Topete,[2] Luis Fernando Lizardi Gomez,[1] Maria T. Gutierrez Gonzalez,[1] Verner Venegas,[1] Abraham E. Gracia-Ramos,[1] Julio D. Rios-Ramirez,[1] Luis E. Álvarez Rangel.[1] *[1]Instituto Mexicano del Seguro Social, Mexico City, Mexico; [2]Hospital Universitario, UANL, Monterrey, Mexico.*

Background: Kidney disease due to COVID-19 is clear, however, there are few data on kidney function (KF) evolution.

Methods: Retrospective cohort conducted at the National Medical Center "La Raza" in Mexico City, Mexico. 252 patients hospitalized from March to June 2020 due to COVID-19 were included. Quantitative variables are expressed as mean ± standard deviation. Odds ratios were calculated to identify associated factors, with a 95% confidence interval.

Results: The mean age was 57.87±15.27 years. The incidence of acute kidney injury (AKI) and acute kidney disease (AKD) were 42.06% (106 cases), 18.87% (20 cases) respectively. A follow-up of at least 12 months of 9 cases was completed, of which 100% developed some stage of chronic kidney disease (CKD). The reason why it was not possible to obtain more data on KF in the rest of the patients was due to loss of follow-up. In the multivariate analysis, the factors associated with AKI were vasopressor (OR: 1.51; CI: 1.44 – 1.59 p <0.001), use of mechanical ventilation (MV) (OR: 1.35; CI: 1.27 – 1.44 p < 0.001), a high value of lactate dehydrogenase P-isoenzyme (OR: 1.32; CI: 1.22 – 1.41 p <0.001) and leukocytosis (OR: 1.23; CI: 1.14 – 1.43 p < 0.001). In the univariate analysis, the factors associated with AKD were coronary artery disease (OR: 5.55; CI: 1.56 - 19.67), use of MV (OR: 4.90; CI: 1.72 - 13.97), mild thrombocytopenia (OR: 4.19; CI: 1.36 – 12.94), use of lopinavir/ritonavir in hospitalization (OR: 3.34; CI: 1.10 – 10.13) and use of angiotensin II receptor antagonist in hospitalization (OR: 3.03; CI: 1.13 – 8.12). In the univariate analysis, the factors associated with CKD were type 2 diabetes (OR: 4.23; CI: 1.03 – 17.34) and the use of lopinavir/ritonavir (OR: 1.13, CI: 1.06 – 1.22). In patients with AKI and AKD associated with COVID-19, a mortality of 64.15% (68 cases, OR: 5.46; CI: 3.16 - 9.44), 80% (16 cases, OR: 4.62; CI: 1.75) was observed. – 12.17).

Conclusions: AKI is a frequent complication in patients with COVID-19, with risk factors involved in its development, as well as in its evolution to AKD or CKD.

PUB012

Serum Electrolyte Profile Among COVID-19 Patients in a Tertiary Health Facility from April to September 2020

Andrew Paul M. Cardoza, Ariel S. Indo. *Vicente Sotto Memorial Medical Center, Cebu City, Philippines.*

Background: Around December of 2019, an outbreak of unknown epidemic was noted in the province of Hubei in Wuhan China. This infectious agent was identified from the SARS family and was termed as 2019-nCoV, the causative agent associated with the COVID 19 disease. The disease was then considered pandemic after it has infected a number of countries across the globe. The aim of this study was to determine the serum electrolyte profile among COVID 19 patients admitted in a tertiary hospital in Cebu City from April to September 2020.

Methods: Retrospective research design was used in the study. The charts of moderate severe and critical cases of COVID 19 admitted at Vicente Sotto Memorial Medical Center from April to September 2020 were reviewed. The investigator collected the patients' age, sex, and co-morbid conditions. Once these data have been collected, the researcher determined the patients' baseline serum electrolytes upon admission. In particular, the serum Sodium, Potassium, and Calcium were obtained. This were classified either as low, normal, or high. This was compared as regards the severity of cases of COVID 19 patients.

Results: Most patients had moderate and critical COVID 19 infections wherein most of these patients were in their late 50s (58.8±15.2). The largest number of patients was male (54.7%). The most prevailing underlying comorbidities, which are more prevalent in men are Hypertension (50.0%) and Diabetes Mellitus (27.7%). Hyponatremia had the largest number of patients (63.9%) common among moderate COVID 19 infection (132.7±5.4). Hyperkalemia was found to develop critical COVID 19 infection (4.4±1.2). Hypocalcemia was common in moderate and critical COVID 19 infection (1.2±0.1 and 1.2±0.2) respectively.

Conclusions: Hyponatremia was observed in the largest number of patients where the largest number of cases of patients had moderate COVID 19 infection. Patients who developed hypernatremia were found to have developed critical COVID 19 infection. There was significant difference in serum potassium when patients were grouped according to severity of COVID 19 infection. Patients with hyperkalemia were found to develop critical COVID 19 infection. Patients with lower serum calcium was found to be at higher risk for developing critical COVID 19 infection. This indicates that serum calcium is a potential biomarker for severe COVID-19 infection.

PUB013

Effect of the Paxlovid on Glomerular Disease Patients

Miguel Uriol Rivera, Estela M. Ródenas, Felipe I. Ojeda, Sonia Jimenez, Aina Obrador. *Hospital Universitario Son Espases, Palma, Spain.*

Background: The reported efficacy of nirmatrelvir-ritonavir (Paxlovid®) in reducing the risk of severe COVID-19 progression in high-risk patients is well-known. However, there is limited evidence regarding its effects on glomerular disease patients (GDP).

Methods: We retrospectively assessed the influence of nirmatrelvir-ritonavir on the risk of death and hospitalization in GDP. We also examined the changes in estimated glomerular filtration rate (eGFR) before and after COVID-19 infection. Proteinuria was defined as urine protein/creatinine ratio > 0.2 mg/mg. Nine patients were included. The mean age of 46 years. Six patients were female. The mean follow-up was 10 months (ranging from 9 to 11). The etiology of glomerulonephritis included ANCA-associated vasculitis (n=2), atypical hemolytic uremic syndrome (n=1), lupus nephritis(n=1), membranous proliferative (n=1) glomerulonephritis, IgA nephropathy (n=2), membranous nephropathy (n=1), and minimal change disease (n=1). Our COVID-19 management protocol involved discontinuing immunosuppression and administering Paxlovid according to the datasheet: nirmatrelvir (2 tables) and ritonavir (1 table) twice a day for 5 days. Weekly oropharyngeal samples were collected for COVID-19 PCR testing to confirm viral negativization, following which immunosuppressants were reintroduced. Four patients had proteinuria before infection.

Results: None of the patients died or required hospitalization. At the time of infection, eGFR decreased by 8.9 mL/min/1.73m2 (P = 0.021); however, it recovered at month six. The presence of proteinuria prior to infection did not significantly affect the trend of eGFR. Furthermore, neither proteinuria levels nor hematuria changed after infection. One patient with lupus nephritis developed long-COVID syndrome and a rapid decline in eGFR. Medication was well tolerated, with only one patient reporting gastrointestinal symptoms.

Conclusions: Paxlovid demonstrated effectiveness in GDP, as no deaths or hospitalizations were required. Importantly, the evolution of eGFR did not show a significant change at the end of the follow-up period, even among patients with pre-existing proteinuria.

PUB014

Ethical Analysis on Mandating COVID-19 Vaccination Prior to Kidney Transplantation in Brazil

Virgílio P. Delgado, Danielle F. Cunha, Alvimar G. Delgado. *Renal Assistência Médica, Rio de janeiro, Brazil.*

Background: With the advent of the COVID-19 pandemic, we saw the debate on the best social protection strategy. In what extent can the principle of individual autonomy be limited by the need for social protection? Would it be licit to limit access to health measures, such as kidney transplantation? The cost of refusing the vaccine has an impact on society, on the transplant program and on other patients admitted to the transplant unit. In kidney transplantation, we have the possibility of analysis and investigation regarding the guiding principles of bioethical decisions, discussing how we should proceed when candidates for transplantation object to vaccination.

Methods: Primary bibliographical research of indexed scientific articles, by the search tools "Google Scholar" and "Pubmed", with the keys of "renal transplantation" and "COVID-19 vaccine refusal". Bibliographical research on technical norms for kidney transplantation and in bioethics books related philosophical and ethical foundations.

Results: The false opposition between autonomy and beneficence is secondary to a market and principialism vision. However, autonomy must be exercised responsibly, in a relational way. It requires a qualified choice, based on an individual's narrative identity with: coherence component and socially shared reality. Several countries have different approaches to conduct. Some with severe restrictions or punishments, some with financial punishments, others discretionary. The reasons for vaccine objection are multiple, we can summarize three main ones: the presence of religious or philosophical motives, medical and willingness to benefit without sharing risks.

Conclusions: Although the authors have different bioethical views, we can draw common points in the construction of a minimum ethics. Most understand the application of coercive measures as a mistake, but that we should value specific situations. To create objective criteria on organ allocation we should acknowledge that the autonomy of the individual is not opposed to social beneficence. The vaccination requirement for deceased donor kidney transplantation is ethically valid. It should be illicit in urgent transplantation, pediatric transplants or related living donor. In the above cases, the patient must accept the universal protection measures determined by the transplant service.

PUB015

A Comparative Study of COVID-19 and Viral Hemorrhagic Fevers

Claudia G. Olano,[1] Andrea L. Urrutia,[2] Sami M. Akram,[3] Nehemias Guevara.[4] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]Universidad de San Carlos de Guatemala, Guatemala, Guatemala; [3]Loma Linda University Medical Center, Loma Linda, CA; [4]St Barnabas Hospital, Bronx, NY.*

Background: Coagulation and platelet dysfunction are hallmarks of covid-19 and viral hemorrhagic fevers (VHF). Agents of VHF have the potential to cause the next pandemic. Examining the differences between the two will help prepare for the next pandemic and efficiently meet the healthcare resources.

Methods: Patients admitted to a community hospital formed the study group between February 2020 and April 2020. A published cohort of viral hemorrhagic fevers formed the historical cohort. The historical VHF cohort case reports were reviewed for comparison. Descriptive statistics were applied. First, the groups were compared using independent t-tests. A p-value of <0.05 was considered significant. Proportions of patients with Lung infiltrates, AKI, and who required MV, ICU, and RRT were then compared using student t-tests. Finally, the proportion of patients who died in the two groups was compared. A P-value of less than 0.05 was considered significant.

Results: COVID-19 group (Covid19 SG) had 51 patients. The control group had 79 cases, of which 61 were selected. The COVID-19 SG had 51 patients. The VHF-CG had 61 patients. Comorbidities included were diabetes, hypertension, and chronic disorders. See Table 1. Diabetes and hypertension were present in 58.8% of patients in the study group. There was no difference in the sex distribution among the groups. The need for mechanical ventilators is five times greater in the COVID-19-SG compared to VHF-CG. See table 2.

Conclusions: The odss ratio of a patient dying becayse of covid-19 alpha variant was six times greater compared to viral hemorragic fever. The need for RRT increases as the ICU stay increases.

TABLE NO.1

COVID-19 SG	N=51	VHF – CG	N = 51	P value
Demographic data				
Mean Age	54.2 (IQR 15)	Mean Age	41.9 (IQR 24)	
Sex M/F	33/18 (Chi square test)	Sex M/F	47/14	0.15
With Comorbidities	32/19 (Chi Square test)	With Comorbidities	4/57	<0.00001

Effect of Phase Angle by Electrical Bioimpedance on the Incidence and Severity of AKI Following Cardiac Surgery

Mauricio Carvallo Venegas,[1] Jorge Andrade-Sierra,[2,1] Enrique Rojas-Campos,[1] Luis G. Gonzalez-Correa,[1] Miguel Medina Perez,[1] Adriana Banda Lopez,[1] Jose Ignacio Cerrillos,[1] Ricardo Parra Guerra,[1] Alfredo Gutiérrez Govea,[1] Luis Alberto Evangelista-Carrillo,[1] Saul Tejeda Del Toro.[1] *[1]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico; [2]Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Bioimpedance (BE) measures the electrical characteristics of the body to evaluate the patient's fluid, nutritional, and pathological condition by measuring resistance, reactance, and phase angle (PA). Low preoperative PA is related to greater morbidity and mortality, although the exact relationship with the development of acute kidney injury (AKI) is unclear. Our objective was to determine whether or not preoperative PA increased the risk for AKI following cardiac surgery.

Methods: Prospective Cohort from Aug-2022-Apr-2023 that included 78 patients ≥18 years old, undergoing elective valve replacement, coronary bypass surgery, or both, in a single surgical procedure. PA was measured 24 hours before surgery and standardized PA was calculated using data from the Mexican population. Serum creatinine was assessed, and the occurrence and severity of AKI were confirmed 7 days following surgery.

Results: The mortality rate was 15% (12 patients) and the incidence of AKI was 30% (23 Pt); 22% (17 Pt) experienced mild AKI, whereas 8% (6 Pt) developed moderate-severe AKI. A PA ≤4.5 was not associated with postoperative AKI and mortality. A standardized PA >-0.54 was related to a lower incidence of mild AKI, 5% (1/20 Pt) vs 28% (16/58 Pt) (p=0.035), with a RR 0.18 (95%CI:0.03-1.16), with no difference in the incidence of moderate-severe AKI and mortality.

Conclusions: PA ≤ 4.5° did not increase the risk of AKI and mortality while a standardized PA >-0.54 could be protective for mild AKI.

	PA ≤ 4.5° = 10	PA >4.5° = 68	p
Age (years)	69 (IQR, 62-76)	63 (IQR, 56-67)	0.028

Comparison of 4 Predictive Scoring Methods as Assessment Tools for Cardiac Surgery Associated-Acute Kidney Injury in Post Coronary Artery Bypass Surgery Patients: A Single-Center Retrospective Study

Cathleen B. Iway, Hariett Torres. *Perpetual Succour Hospital, Cebu City, Philippines.*

Background: Cardiac surgery associated acute kidney injury (CSA-AKI) is a common cause of hospital acquired-AKI precipitated by perioperative factors. The surgery itself is a renal stressor and post operative kidney function is an important predictor of morbidity and mortality. Various objective, bedside predictive models were developed to risks stratify patients who would likely develop CSA-AKI. This study is to determine the most sufficient scoring system to be utilized by comparing 4 predictive models that may help facilitate clinical decision making, early preventive strategies and patient counselling.

Methods: A chart review was done to all patients who underwent open heart surgery last January 2010 to January 2019. Patients who developed AKI after cardiac surgery were identified and binary logistic regression was used to describe the relationship between the development of CSA-AKI and the four scoring methods as its predictors. Confidence interval is set at 95%, comparison significant at <0.05, hypotheses tested at 0.05 level of significance. Therefore, if the p-value is less than or equal to the significance level, it can be concluded that there is a statistically significant association between the response variable and the predictor.

Results: There were a total of 114 cases of open heart surgeries. A sample size population of 86 were reviewed. There were 43 patients (50%) who developed CSA-AKI wherein 5 patients (5.81%) eventually progressed to renal replacement therapy. The p-values for the Cleveland Clinical Score and Simplified Renal Index are greater than the significance level. With the p-values less than the significance level, there is statistically significant association between the Mehta (p value 0.019) and AKICS score (p value 0.011) and the development of CSA- AKI. The odds ratios for both Mehta Score (1.10) and AKICS Score (1.19) are also greater than 1, indicating that AKI is more likely to occur if the Mehta score or the AKICS Score increases.

Conclusions: In this single-center study, AKI was more likely if the scores for both Mehta and AKICS scoring system methods increase. This supports that either Mehta or the AKICS scoring systems are useful methods that can be employed to predict CSA-AKI among patients who underwent coronary artery bypass.

PUB018

Incidence, Risk Factors, and Outcomes of Postoperative AKI in China: A Multicenter Retrospective Analysis

Shuwang Ge, Yichun Cheng. *Tongji Hospital Affiliated to Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Postoperative acute kidney injury (AKI) is a common condition after surgery, however, the available data about nationwide epidemiology of postoperative AKI in China from the large and high-quality studies is limited. This study was aimed to determine the incidence, risk factors, and outcomes of postoperative AKI among patients undergoing surgery in China.

Methods: This was a large, multicenter, retrospective study performed in 16 tertiary medical centers in China. Adult (at least 18 years old) patients who undergoing surgical procedures from January 1, 2013 to December 31, 2019 were included. Postoperative AKI was defined by the Kidney Disease: Improving Global Outcomes creatinine criteria. The associations of AKI and in-hospital outcomes were investigated using logistic regression models adjusted for potential confounders.

Results: Among 520707 patients included in our study, 25830 (5.0%) patients developed postoperative AKI. The incidence of postoperative AKI varied by surgery type, which was highest in cardiac (34.6%) surgery, followed by urologic (8.7%), and general (4.2%) surgeries. 89.2% postoperative AKI cases were detected in the first 2 postoperative days. However, only 584 (2.3%) patients with postoperative AKI were diagnosed with AKI on discharge. Risk factors for postoperative AKI included advanced age, male sex, lower baseline kidney function, pre-surgery hospital stay≤3 days or > 7 days, hypertension, diabetes mellitus, and use of PPIs or diuretics. The risk of in-hospital death increased with the stage of AKI. In addition, patients with postoperative AKI had longer length of hospital stay (12 vs 19 days), were more likely to require intensive unit care (13.1% vs 45.0%) and renal replacement therapy (0.4% vs 7.7%).

Conclusions: Postoperative AKI was common across surgery type in China, particularly for patients undergoing cardiac surgery. Raising the awareness and development of an alarm system is important for the battle against postoperative AKI.

PUB019

Outcomes of AKI Hospitalizations Among Patients with Heart Failure and Atrial Fibrillation: A Nationwide Analysis

Iskandar Berbari,[1] Michael A. Fatuyi,[1] Muayad Alzamara,[1] Mohammad Amin Eshghabadi,[1] Funlola O. Bada,[2] Amit K. Rajput.[1] *[1]TriHealth, Cincinnati, OH; [2]St Ann Bay, St Ann, Jamaica.*

Background: Acute Kidney Injury (AKI) has a high incidence among patients with heart failure (HF) and atrial fibrillation (AF). The primary aim of our study is to compare rates of in-hospital mortality and morbidity for patients admitted with AKI only, AKI with AF, AKI with HF, and AKI with both HF & AF.

Methods: This is a retrospective study with data obtained from the National Inpatient Sample database. We included all adults who were admitted with a principal diagnosis of AKI between 2018 & 2020. The cohort was stratified into patients with AKI only, AKI with AF, AKI with HF, and AKI with both HF and AF. The primary outcome was inpatient mortality. Secondary outcomes included acute coronary syndrome, cardiogenic shock, STEMI, length of stay (LOS), average hospital cost, average patient charge, and acute respiratory failure. Univariate and Multivariate Logistic, Linear & Poisson regression model were used for analysis.

Results: Patients with AKI alone had the lowest rates of in-hospital mortality (1.45%). Compared to the AKI only group, patients with AKI and AF had higher rates of in-hospital mortality (2.90%), acute coronary syndrome (3.64%), STEMI (0.92%), cardiac arrests (0.68%), cardiogenic shock (0.20%), acute respiratory failure (7.31%), and septic shock (1.27%), with an average LOS of 4.93 days and an average patient charge of $43,564. Compared to the AKI only group, patients with AKI and CHF had even higher rates of in-hospital mortality (2.77%), cardiac arrests (0.32%), cardiogenic shock (0.064%), acute respiratory failure (15.95%) and septic shock (1.29%), with an average length of stay of 5.39 days and an average patient charge of $49,126. AKI patients with both AF and CHF had the poorest outcomes, with higher rates of in-hospital mortality (4.38%), acute coronary syndrome (4.54%), STEMI (1.16%), cardiac arrests (0.96%), cardiogenic shock (1.21%), acute respiratory failure (17.67%), septic shock (1.40%), with an average length of stay of 5.51 days and an average patient charge of $49,153.

Conclusions: In conclusion, our study demonstrated that mortality and morbidity is significantly higher in patients with concurrent cardiac co-morbidities, compared to AKI alone. There was an incremental increase in poorer outcomes with AF, CHF, and combined CHF with AF, respectively.

PUB020

Racial Disparities Following Severe AKI

Andrew Zhang, Svati Pazhyanur, Elizabeth Spranger, Jonathan Wang, Michael Heung. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Acute kidney injury requiring dialysis (AKI-D) is a severe complication during acute hospitalizations. AKI survivors remain at risk for adverse outcomes and follow-up care has been shown to be suboptimal. The goal of this study was to identify any racial disparities in post-AKI follow-up care and outcomes, laying the groundwork for future interventions to reduce racial disparities.

Methods: Single-center retrospective analysis of consecutive patients with AKI-D in 2021 who were discharged alive and off dialysis. Patients discharged to hospice or with a history of ESRD or kidney transplant were excluded. Patient demographics, labs, documented education, follow-up recommendations, and 12m post-discharge outcomes were collected.

Results: A total of 78 patients were included: mean age 57y, 71% male, mean baseline eGFR 64. Mean duration of dialysis was 12d and hospital length of stay 41d. Most patients self-identified as White (55, 70%) or Black (18, 23%), so analyses were limited to comparing these groups. 72% of Black patients had a documented recommendation for post-discharge nephrology follow-up compared to 31% of White patients (p = 0.002). Among these patients, 54% of Black patients completed follow-up compared to 94% of White patients. Overall, 39% of Black patients and 29% of White patients followed up with a nephrologist. 12-month mortality was over four times higher for African American patients than Caucasian patients (p = 0.036).

Conclusions: Compared to White patients, Black patients were more likely to have a nephrology follow-up visit recommended as well as completed. Despite this, Black patients had lower survival compared to Caucasian patients. These findings suggest the need to explore additional, modifiable factors to reduce excess mortality experienced by this population.

Evaluating the Consequences of Delirium on Patient Outcomes During Hospitalizations for AKI

Anish Surapaneni,[1] Akil S. Kavcar,[2] Meghana Vallabhaneni,[2] Cameron T. Lawson,[2] Chadi Y. Saad.[1] *[1]Garden City Hospital, Garden City, MI; [2]East Carolina University, Greenville, NC.*

Background: Delirium frequently accompanies acute kidney injury (AKI) during hospitalizations and can lead to increased healthcare usage and poorer outcomes. This study delves into the specific impact of delirium on AKI hospitalizations.

Methods: We conducted a cohort study using the National Inpatient Sample (NIS) database from 2019-2020. The International Classification of Disease-10 codes were used to identify hospitalizations with AKI as the principal diagnosis and then stratified them based on whether they had delirium. The outcomes that were measured included in-patient mortality, length of stay, total hospital charges, and complications during the hospitalization. We used multivariate regression analysis to adjust for confounders.

Results: Of 9,121,794 AKI hospitalizations, delirium was present in 198,664. The delirium group had a higher average age (74 vs. 67, p <0.001), with a majority being male (56%, p=0.003) and Caucasian (66%, p<0.001). After adjusting for patient demographics, comorbidities, and hospital characteristics, delirium-associated hospitalizations demonstrated significantly higher odds of mortality (aOR=1.19, p<0.001, CI: 1.14 - 1.25), acute ischemic stroke (aOR= 1.4, p<0.001, CI: 1.34 - 1.46), acute respiratory failure (aOR= 1.18, p<0.001, CI: 1.09 - 1.28) and acute coronary syndrome (aOR= 1.06, p=0.003, CI: 1.02 - 1.1). Length of stay (coefficient=6.85, p<0.001, CI: 6.62 - 7.12) and total hospital charges (coefficient=96,303, p<0.001, CI: 86976 - 105629) were also increased in the delirium group.

Conclusions: AKI hospitalizations with concurrent delirium exhibited worse outcomes in terms of mortality, length of stay, total hospital charges, acute ischemic stroke, acute respiratory failure, and acute coronary syndrome. This highlights the critical need for early identification and management of delirium in AKI hospitalizations.

PUB022

The Influence of AKI on Patient Outcomes in SARS-CoV-2 Pneumonia Hospitalizations

Anish Surapaneni,[1] Akil S. Kavcar,[2] Meghana Vallabhaneni,[2] Cameron T. Lawson,[2] Chadi Y. Saad.[1] *[1]Garden City Hospital, Garden City, MI; [2]ECU Health, Greenville, NC.*

Background: Acute Kidney Injury (AKI) is a recurrent complication in patients with SARS-CoV-2 pneumonia, often leading to adverse outcomes and inflated healthcare costs. The aim of this study was to elucidate the effects of AKI on mortality and other in-hospital outcomes in SARS-CoV-2 pneumonia hospitalizations.

Methods: We conducted this study using the National Inpatient Sample (NIS) database from 2020. SARS-CoV-2 pneumonia hospitalizations were identified, classified, and stratified by AKI presence using International Classification of Diseases-10 codes. Mortality served as the primary outcome, with in-hospital complications as secondary outcomes. Confounding factors were adjusted through multivariate regression analysis.

Results: Out of 1,058,815 hospitalizations with SARS-CoV-2 pneumonia, 265,925 involved AKI. Patients with AKI were typically older (median age 70 vs 62, P<0.001), predominantly male (51%, P<0.001), and Caucasian (53%, P<0.001). Total hospital charges and average length of stay were significantly higher in the AKI group by $53,132 (P<0.001) and 2.67 days (P<0.001), respectively. Figure 1 illustrates the adjusted odds ratios for complications and mortality.

Conclusions: AKI presence in SARS-CoV-2 pneumonia hospitalizations is associated with increased mortality risk, in-hospital complications, length of stay, and total hospital charges. These findings underscore the necessity of prompt AKI detection and management in this patient population.

Development and Validation of a Least Absolute Shrinkage and Selection Operator (LASSO) Prediction Model for Cisplatin-Induced Nephrotoxicity: A Case-Control Study in China

Fei Deng,[1,2] Shijie Ma,[1] Wei Zhou,[1] Yuwei Kang,[1,3] Wei Yang.[1,3] *[1]Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China; [2]Chengdu Jinniu District People's Hospital, Chengdu, China; [3]The Affiliated Hospital of Southwest Medical University, Luzhou, China.*

Background: Early identification of high-risk individuals with cisplatin-induced nephrotoxicity (CIN) is crucial for avoiding CIN and improving prognosis. In this study, we developed and validated a CIN prediction model based on general clinical data, laboratory indications, and genetic features of lung cancer patients before chemotherapy.

Methods: We retrospectively included 696 lung cancer patients using platinum chemotherapy regimens from June 2019 to June 2021 as the test set to construct a predictive model using Absolute shrinkage and selection operator (LASSO) regression, cross validation, and Akaike's information criterion (AIC) to select important variables. We prospectively selected 283 independent lung cancer patients from July 2021 to December 2022 as the validation set to evaluate the model's performance.

Results: The prediction model showed good discrimination and calibration, with AUCs of 0.9217 and 0.8288, sensitivity of 79.89% and 45.07%, specificity of 94.48% and 94.81%, in the test and validation sets respectively. Clinical decision curve analysis suggested that the model has value for clinical use when the risk threshold ranges between 0.1 and 0.9.

Conclusions: Predictive models based on laboratory and demographic variables can serve as a beneficial complementary tool for identifying high-risk populations with CIN.

PUB024

Association Between Serum Osmolality and AKI in Critically ill Patients: Prospective Observational Study

Khairwar Mahesh Prasad, Aditya S. Handargule, Alan F. Almeida, Rasika Sirsat, Ayan K. Dey. *PD Hinduja National Hospital and Medical Research Centre, Mumbai, India.*

Background: AKI is common in hospitalised patients and especially in critically ill patients. There has been growing research on AKI concerning biomarkers of renal injury to predict AKI. These markers are not readily available and cost constraints have limited their use in Indian settings. There have been limited studies that have used serum osmolality as a tool to determine the volume status and predict AKI. We wanted to study whether low or high serum osmolality was associated with new-onset AKI and mortality during the ICU stay.

Methods: The study was a prospective observational study conducted on patients admitted to the ICU of tertiary care hospital in India. From April 2022 to Jan 2023, 1300 patients were recruited. Patients having abnormal creatinine at baseline were excluded at time of admission. Serum osmolality was calculated at the time of admission. Serum osmolality of 280-295 mmol/l was considered normal. Patients were followed up for the development of AKI and mortality during their stay in ICU. Univariate and Multivariate analysis was done for various cofactors and AKI and Mortality in ICU.

Results: Incidence of AKI was 26%**.** Abnormal serum osmolality showed a significant association with AKI. Abnormal serum osmolality had an OR 12.97 (CI 9.24-18.2)**.** On sub-analysis of patients with abnormal serum osmolality, there was an incidence of AKI was 44.25% (OR:11.14 CI 7.9 -15.70) in the group with low serum osmolality and 81.97% (OR: 63.8 CI 31.13-130.88) in the group with high osmolality as compared with 6.65% in patients with normal osmolality (p<0.0001). AKI had a significant association with mortality in ICU with a prevalence of 78.6% (p < 0.0001). High or low serum osmolality was independently associated with an increased risk of mortality with low osmolality < 280 having an odds ratio of 3.1056 (CI 1.63-5.88) and high serum osmolality > 295 having an odds ratio of 13.11 (CI 5.83-29.47).

Conclusions: Both high and low serum osmolality at the time of admission were independently associated with an increased risk of development of AKI compared with normal serum osmolality. Low and high serum osmolality was associated with an increased risk of mortality during the stay in the ICU.

PUB025

Incidence, Etiology, and Outcome of AKI in the Coronary Care Unit: A Retrospective Study from a Single Center in Thailand

Solos Jaturapisanukul, Supassara Nimkulrat, Punnawit Laungchuaychok, Wanjak Pongsitisak. Vajira Renal-Rheumatology-Autoimmune Disease Research Group. *Navamindradhiraj University, Bangkok, Thailand.*

Background: AKI can lead to complications such as fluid overload, uremic symptoms, electrolyte disturbance, and metabolic acidosis. It is associated with increased morbidity, mortality, and incidence in critically ill patients. However, data on AKI in the CCU in the low to middle income countries are limited. This study aims to assess AKI incidence, etiology, risk factors, survival rate, and occurrence of ESKD and KRT in CCU patients in Thailand.

Methods: A retrospective cohort study was undertaken on patients admitted to the CCU at Vajira Hospital, a tertiary care facility located in Bangkok, Thailand, from January 2019 to September 2020. The analysis encompassed various factors including baseline characteristics, comorbidities, CKD stage, medications, volume of contrast media, hypotension upon admission, use of inotropes, mechanical ventilator utilization, as well as EKG and CXR characteristics.

Results: Of 209 eligible patients admitted to CCU in Vajira hospital, AKI has occurred in 64 (31%) patients. The most common diagnosis of AKI was an acute tubular injury (ATI) which occurred in 27 (42%) patients. At both 30 and 90 days, it was found that AKI was associated with higher rates of all-cause mortality Patients with AKI had an overall mortality rate of 36% (23/64 patients) at 30-days compared to 1% (5/145 patients) in those without AKI, p <0.001 and a 90-days mortality rate of 44% (28/64 patients) compared to 7% (10/145 patients) in those without AKI, p <0.001. Mortality also increased with AKI severity. There were significant differences in survival (log-rank, p <0.001) in the Kaplan–Meier survival analysis between non-AKI and AKI groups. Multivariate analysis shows risk factors associated with AKI were CKD stage 3 and CKD stage 5, inotropic use, reduced left ventricular ejection fraction, and on a mechanical ventilator, respectively. Furthermore, an increase in age, CKD stage 5, atrial fibrillation, and inotrope use are associated with kidney replacement therapy.

Conclusions: AKI is common in patients admitted to the CCU. Patients with AKI are associated with higher mortality and progression to ESKD compared to non-AKI patients. Inotropic use, reduced Left ventricular ejection fraction, on a mechanical ventilator, and CKD were the risk factors associated with AKI.

PUB026

Atypical Hemolytic Uremic Syndrome Secondary to Transcatheter Aortic Valve Replacement (TAVR)

Solabomi O. Ojeniyi, Dina R. Gonzalez Hernandez. *MedStar Union Memorial Hospital, Baltimore, MD.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare subtype of TMA mediated by complement dysregulation with an incidence of 0.23-0.43 cases per million population. It can manifest in a diverse range of conditions and presentations, but acute kidney injury is a common prominent feature because of the apparent propensity of the glomerular circulation to endothelial damage and occlusion. We present a case of aHUS developed after an elective TAVR.

Case Description: An 86-year-old man with PMH of aortic stenosis who presented for an elective TAVR which was successfully done. However, post-operative day 1, he developed new onset hematuria [dark brown to tea colored urine] and elevated BUN/ Creatinine [Baseline serum creatinine of 0.9 to 1 mg/dL. He continued to have hematuria and worsening renal function. Laboratory studies were remarkable for thrombocytopenia, low haptoglobin, and low fibrinogen. Normocytic anemia. Schistocytes on peripheral smear. Elevated D-dimer, CK, LDH, total bilirubin, direct bilirubin, AST. ADAMS 13 activity was greater than 5%. UA showed trace blood and 4-5 RBC. Complements, vasculitis panel, hepatitis panel, coagulation panel, cryoglobulinemia, and direct antiglobulin test were all negative. The patient remained asymptomatic throughout the hospital stay. He was managed symptomatically with antihypertensives for blood pressure control, intravenous hydration with normal saline, and platelet transfusion for thrombocytopenia. With the improvement of renal function, thrombocytopenia, and resolution hematuria. The patient was discharged home to follow-up with Nephrology and hematology.

Discussion: Atypical hemolytic uremic syndrome is most commonly due to a loss of function of a regulatory protein either by genetic mutation or autoantibody. The most common triggers include infections, autoimmune conditions, drugs, malignancies, or pregnancy. Treatment can be supportive, plasma exchange and anticomplement therapy. Although aHUS are associated with significant mortality and morbidity, including end-stage renal disease [ESRD], prompt diagnosis and initiation of supportive and specific management can transform outcome.

PUB027

External Validation of a Simple Prediction Model for AKI After Noncardiac Surgeries

Youlu Zhao, Jinwei Wang, Damin Xu, Jicheng Lv, Li Yang. *Peking University First Hospital, Beijing, China.*

Background: The Simple Postoperative AKI Risk (SPARK) index is a practical prediction model for postoperative acute kidney injury (PO-AKI) in patients undergoing non-cardiac surgery. Its universality needs more verification.

Methods: This single-center retrospective cohort included adults who had surgery under general anesthesia from 2018 to 2020 at Peking University First Hospital **(Figure 1).** PO-AKI was defined according to KDIGO-Scr criteria. Critical AKI was defined as AKI stage 2 or greater or requiring dialysis. The area under the receiver operating characteristic curves (AUC) and the Hosmer-Lemeshow test were assessed.

Results: Among 8484 participants, 4710 (55.52%) were male, 183 (2.16%) developed PO-AKI stage 1, and 55 (0.65%) developed critical AKI. Compared with the SPARK cohort, participants in our cohort were older (median [IQR] age, 61 [49-69] years vs 56 [44-66] years) and had a higher prevalence of dipstick albuminuria (urine albumin ≥1+) (37.61% vs 9.3%)**.** The incidence of PO-AKI and critical AKI increased as the scores on the SPARK index increased **(Figure 2a)**. The SPARK index showed fair discrimination and calibration power for both the PO-AKI and the critical AKI **(Figure 2b,c,d,e).**

Conclusions: SPARK index can be a reliable tool for predicting PO-AKI and identifying high-risk patients in Chinese population.

PUB028

Diffuse Alveolar Hemorrhage in ANCA-Associated Vasculitis with Renal Involvement

Stella O. Ogbonna. *Novant Health New Hanover Regional Medical Center, Wilmington, NC.*

Introduction: Diffuse alveolar haemorrhage (DAH) is a potentially life-threatening feature of ANCA-associated vasculitis (AAV) which is caused by disseminated injury of pulmonary capillaries with an incidence of 1 in 20,000 annually in the United States. Though plasmapheresis (PLEX) is part of the recommended treatment, our case highlights that the early diagnosis and initiation of steroids and Rituximab even without PLEX is paramount for survival.

Case Description: A 79-year-old hispanic male with prior history of renal disease, recent ANCA positive with indeterminate results on renal biopsy was admitted with several days of dyspnea on exertion associated with hemoptysis. Chest x-ray consistent with pneumonia, physical examination was remarkable for coarse respiratory sounds. Required intubation and mechanical ventilation due to worsening of respiratory failure. Underwent renal failure, and dialysis was initiated. After intubation, he underwent emergent bronchoscopy and was noted to have sequential in all liquids with diffuse alveolar haemorrhage, receiving 1 pRBC for acute blood loss anaemia. Repeat chest x-ray showed worsening bilateral pulmonary edema vs haemorrhage. CT chest without contrast revealed extensive alveolar consolidation. ANA, C3, C4, Anti GBM Ab, acid fast bacilli, pneumonia and respiratory panel were unremarkable. He immediately received pulse dose steroids on arrival to the ICU and Rituximab once daignosis was made. He was successfully extubated on day 4 and discharged on steroid taper, followed up with Rheumatology and Nephrology for Rituximab treatment on day 15.

Discussion: Though the MEPEX trial strongly supports PLEX treatment in our case, the PEXIVAS trial showed that the use of PLEX did not improve survival. Our case challenges the use of PLEX and also showed complete recovery with treatment with prednisone and rituximab. The role of plasmapheresis as adjunctive therapy remains to be established. The role of plasmapheresis is unclear, and based on data review it didn't show

superiority when compared to treatment with high doses of steroids and Rituximab. Early treatment in DAH is fundamental for survival. More studies need to be done to prove the benefits of PLEX in DAH and to support treatment without it, especially in facilities where plasmapheresis access is limited. This case supports the theory of early treatment with good outcomes despite no PLEX.

PUB029

AKI and Its Outcome in Filipinos 100 Days After Hematopoietic Stem Cell Transplantation: A Single-Center Retrospective Study

Leo Guillermo T. Villalobos. *The Medical City, Pasig City, Philippines.*

Background: Hematopoetic stem cell transplantation (HSCT) is a complex life-saving procedure that had significantly made an impact in the management of various hematologic disorders. However, it exposes patients to several complications such as infusion reactions, medication side effects, infections, graft rejection, kidney injury, and cardiovascular events. Acute kidney injury (AKI), in particular, is a common complication linked to higher morbidity and mortality affecting the overall outcome of HSCT. Locally, data focusing on HSCT is very limited due to the modest increase in transplant procedures recording only 207 cases until the year 2018. Hence the study aimed to determine the incidence of AKI and its outcomes in Filipinos who underwent HSCT in a single tertiary hospital.

Methods: The study included Filipino patients aged 18 years and above, and excluded those who were maintained on dialysis during the time of transplantation. Data were collected retrospectively by chart review from July 2016 to June 2022, consisting of patients' demographics and medical history, laboratory results, HSCT details and the reported complications.

Results: A total of 49 patients were included, with a mean age of 47 years, 42% were male, 36% were hypertensive, 12% were diabetic and 12% had chronic kidney disease. Baseline creatinine showed a mean of 0.83 ± 0.27mg/dL and a mean eGFR of 95.7 ± 21.84mL/min/1.73m^2. AKI was documented in 14% of patients, with a median of 28 days (18 to 44) from the day of transplant, median creatinine of 1.22mg/dL (1.07 to 1.29) and a median peak creatinine of 1.32mg/dL (1.23 to 1.48). The study showed that AKI was statistically higher in allogeneic transplants (p <0.001) and in those who had an acute graft versus host disease (aGHVD) (p 0.001). Infections (p 0.012) and exposure to carbapenems (p 0.041) were also associated with increased risk of AKI after HSCT. Clinical outcomes such as length of hospital stay (p 0.003), readmissions (p 0.031) and mortality (p 0.016) were all statistically significant in patients with AKI.

Conclusions: AKI is a common complication in Filipinos following HSCT and is associated with increased mortality, longer hospital stay and higher rate of readmissions. The presence of factors such as allogeneic HSCT, infections, and aGVHD predisposes patients to higher risk of AKI 100 days after HSCT.

PUB030

No, It's Not Bilateral Hydronephrosis: It's Pseudohydronephrosis!

Macaulay A. Onuigbo, Jessica Okrant. *University of Vermont Larner College of Medicine, Burlington, VT.*

Introduction: Bilateral hydronephrosis remains the sine qua non diagnostic criterion for clinically relevant obstructive uropathy. Therefore, renal sonograms are often utilized for this diagnostic step. Conversely, pseudohydronephrosis, renal imaging characteristics that mimic obstructive uropathy without obstructive pathology has only been very scantily reported.

Case Description: An 80-year-old male with coronary artery stent in 2005 was diagnosed in November 2022 with biopsy-proven pure red cell aplasia. He started cyclosporine 3mg/kg BID and prednisone 25mg/day. He was admitted two months later with HSV1-positive facial and oral lesions and started Valacyclovir 1000mg BID. He had no urinary or other systemic symptoms except weight loss from reduced food intake. Vital signs were stable. Serum creatinine was 1.58 mg/dL in October 2022, 1.81 mg/dL on admission, with hyperkalemia, 5.7 mmol/L. Trough cyclosporine was 169 ng/mL. Bactrim, lisinopril, and atorvastatin were held. Renal sonogram showed bilateral moderate hydronephrosis (A,B). Follow-up contrast- enhanced-CT demonstrated cortical atrophy, multiple renal sinus cysts but otherwise no urinary obstruction (C,D). Serum creatinine, one week later improved to 1.61 mg/dL, and potassium was 5.1 mmol/L. The discharge diagnosis was pseudohydronephrosis.

Discussion: Pseudohydronephrosis, very rarely reported, was first described in 1953. Unnecessary expensive, invasive, and potentially dangerous investigations and procedures must be avoided. Clearly, the absence of hydroureters concurrent with bilateral hydronephrosis on the sonogram should have triggered thoughts about pseudohydronephrosis. Kidney function improved without any additional surgical intervention. It is not obstructive uropathy – it is pseudohydronephrosis!

Safe and Effective Implementation of a Regional Citrate Anticoagulation Protocol in an Emergency Use Situation

David Catanzaro,[1] Stephen J. Amerson,[2] Matthew Jacques,[1] Fadi Abouzahr,[3] Mohammed Ahmad,[4] Rachel Sterling,[2] Hitesh V. Gidwani,[5] Linda E. Sousse,[2] Kevin K. Chung,[1] Sai Prasad N. Iyer,[1] H. David Humes.[6] *[1]SeaStar Medical, Cincinnati, OH; [2]Methodist Healthcare System of San Antonio Ltd, San Antonio, TX; [3]Renal Associates PA, San Antonio, TX; [4]San Antonio Kidney Disease Center, San Antonio, TX; [5]Texas IPS, San Antonio, TX; [6]University of Michigan, Ann Arbor, MI.*

Introduction: Despite the fact the KDIGO guidelines recommend using regional citrate anticoagulation (RCA) over heparins in CRRT, unfractionated heparin remains the most widely used anticoagulant worldwide. Advantages include: wide availability, large body of experience, short half-life, an available antagonist and low costs. Disadvantages include: a narrow therapeutic index (bleeding risk), unpredictable kinetics and heparin resistance. At our institution, standard practice for anticoagulation in CRRT utilizes two separate heparin boluses prior to initiation and again after start of therapy. RCA is only used at our site if the patient is on plasmapharesis and allergic to heparin or for physician preference.

Case Description: We recently employed the emergency use of the investigational selective cytopheretic device (SCD) in saving the life of a 28 year old woman (5 days post cesarean-section) who developed streptococcal toxic shock syndrome and multi-organ failure. The SCD is a cell-directed extracorporeal therapy that promotes an immunomodulatory effect of the host septic response when the CRRT circuit ionized calcium is maintained at <0.40 mmol/L with regional citrate anticoagulation. As the SCD is an investigational device, our institution obtained the device via an emergency use request directly with the device company. Within 3 days of our request, we were able to initiate therapy in the patient. The device company sent a nurse educator to our institution to oversee staff training on device implementation and RCA anticoagulation protocol. This report will summarize our experience initiating this protocol in an urgent setting with staff who had limited experience with RCA.

Discussion: Potential hesitations with implementing an RCA protocol at other sites might include costs, access and complexity of use. Best practices we can share from our experience include proper communication with pharmacy and our lab. This ensures we have the correct 1L bags for infusion and the proper identification of iCa collection site. Protocol complexities can be addressed with proper staff training for ordering the infusion rate based on the algorithm in the protocol shared with our site.

PUB032

AKI Induced by Cryptosporidium in a Patient with Acquired Immunodeficiency Syndrome

Yi Hsin Chou.[1,2] *[1]Taipei City Hospital Zhongxing Branch, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Introduction: Cryptosporidiosis is a global disease that causes infectious enteritis in immunocompromised patients, which results in volume reduction, loss of sodium, potassium, as well as bicarbonate. It has not been previously published that cryptosporidiosis can bring about kidney disease in Human Immunodeficiency Virus(HIV) infected adults. Here, we present a patient with acute kidney injury induced by Cryptosporidium.

Case Description: A 33-year-old man presented with general weakness and watery diarrhea for several days. He was diagnosed of AIDS three months ago but did not take any antiviral agents afterward. He had dry oral mucosa, dry skin turgor, mild diffuse abdominal tenderness, and symmetrically decreased proximal muscles strength. Laboratory exams

revealed serum sodium(Na) 128 mmol/L, potassium(K) 1.6 mmol/L, chloride(Cl) 107 mmol/L, bicarbonate 10 mmol/L, pCO2 24.1 mmHg, blood urea nitrogen 100 mg/dL, creatinine 4.2 mg/dL, serum pH 7.23, CD4 count 47/uL (Table). Urinalysis unveiled creatinine 106.7 mg/dL, Na 5 mmol/L, K 5.1 mmol/L, Cl 15 mmol/L. He was treated with saline infusion, intravenous potassium chloride, and oral potassium gluconate. Watery diarrhea persisted. His stool PCR was detected positive for Cryptosporidium parvum. Triumeq tablet was prescribed on the fourth day. Diarrhea subsided gradually, and no more potassium supplement was needed.

Discussion: Kidney injury and hypokalemia can be attributed to significant loss from diarrhea in our case. It reminds us that Cryptosporidium may be a crucial origin of kidney disease in HIV patients with poor compliance to anti-viral treatment. Hypokalemia, azotemia and metabolic acidosis implies intestinal loss of potassium and bicarbonate. Aggressive fluid supplement, close monitor and rapid replenish of electrolytes imbalance assist renal function full recovery. Antiretroviral therapy remains the most important treatment.

Level of kidney function, sodium, potassium and stool amount.

Hospital day	BUN (mg/dL)	Creatinine (mg/dL)	Sodium (mmol/L)	Potassium (mmol/L)	Stool amount (g)

Kinetic Formula (KeGFR) for the Estimation of Glomerular Filtration Rate in a Mexican Population with AKI

Karen Hopf, J. Perez, Nuri P. Campos, Roberto Galindo, Damayanty Gomez.
Hospital General Tacuba, Mexico City, Mexico.

Background: Acute kidney injury (AKI) management requires drug dosage adjudgment based on glomerular filtration rate (GFR). Commonly used calculators like MDRD (Modification of Diet in Renal Disease) and CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) estimate glomerular filtration rate based on a steady-state creatinine. The KeGFR (Kinetic Estimated Glomerular Filtration Rate) calculator has been used to better estimate the GFR in states of rapidly changing creatinine. The following study aimed to identify the usefulness of KeGFR in Mexican patients with AKI and calculate the concordance between this calculator and commonly used MDRD and CKD-EPI.

Methods: Prospective trial, 60 patients with AKI hospitalized in December 2022. Patients with chronic kidney disease were excluded. GFR was estimated with digital calculators. Three categories were established (<30, 30-49 and >50 mL/min) based on need for drug dosage adjustment. Distribution of episodes was calculated for every category, as was mean and concordance coefficient. A $p<0.05$ was considered significant. STATA® 14.0 was used.

Results: KeGFR found a greater number of episodes and had the smallest mean in the lowest GFR category <30 ml/min (Table 1-2). Also, calculators became less concordant as the GFR declined (table 3).

Conclusions: KeGFR could be a useful tool in Mexican patients with rapidly changing creatinine values since it results in a lower GFR which in turn would lead to more drug dosage adjustments, protecting patients from nephrotoxic effects. To complement this trial, the glomerular filtration rate should be measured with an exact method like cystatin c to determine the concordance with the calculators.

Distribution of patient episodes in the eGFR categories by the 3 estimation methods

eGFR category	KeGFR	MDRD	CKD-EPI
>50	17	17	20
30-49	14	19	15
<30	29	24	25

Table 1

Mean between eGFR categories by the 3 estimation methods

eGFR category	KeGFR	MDRD	CKD-EPI
>50	68 ± 19	70 ± 20	71 ± 20
30-49	40 ± 5	39 ± 5	40 ± 3
<30	14 ± 8	16 ± 6	17 ± 7

Table 2

Agreement between GFR categories by concordance correlation coefficient (CCC)

eGFR category	KeGFR vs MDRD	KeGFR vs CKD-EPI	MDRD vs CKD-EPI
>50	0.856 (0.718 - 0.994)	0.795 (0.618 - 0.973)	0.945 (0.896 - 0.994)
30-49	0.850 (0.543 - 0.947)	0.519 (0.066 - 0.972)	0.725 (0.542 - 0.907)

Blood Urea Nitrogen and Urinary Output as Renal Recovery Factors After Continuous Renal Replacement Therapy (CRRT) in Critically Ill Patients with AKI

Paola Borbolla,[1] Leonardo Rodriguez,[1] Natalia L. Garza,[1] Lilia M. Rizo Topete.[1,2]
[1]*Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico;*
[2]*Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Background: Due to the lack of standardization for continuous renal replacement therapy (CRRT) cessation and predictive factors that help determine renal recovery, the need for new research about this topic is essential. The aim of our study is to assess renal recovery capacity based on predictive factors such as urine output (UO), albumin, creatinine, and blood urea nitrogen (BUN). This study was carried out with patients admitted to the intensive care unit (ICU) in a hospital in northern Mexico, with acute kidney injury (AKI) that required CRRT.

Methods: A retrospective, observational and descriptive study from January 2019 to 2023 in ICU. Patients with AKI requiring CRRT. The population was divided into two groups: I) patients who recovered renal function as prior to therapy; and II) patients who did not recover renal function.

Results: A total of 39 subjects were analyzed, 29 (74.4%) were men; mean (SD) age 66 (14). 16 (41.1%) patients are overweight, and 8 (20.5%) have diabetes. The dependent variable was renal recovery. The independent variables significantly positive were UO and BUN 24 hours after the start of CRRT. In the inferential statistics, a linear regression model was performed, which showed that UO (p 0.030) and BUN 24 hours after CRRT initiation (p 0.028) help us to predict renal recovery.

Conclusions: There is an association between UO and BUN 24 hours after the start of CRRT with renal recovery. We can compare the results with other studies which take urine output as the indicator for cessation CRRT therapy and possible renal recovery. It is important to continue searching for predictors of renal recovery. Lately the proenkephalin (PENK) has been studied as a biomarker and predictive factor of renal, damage and recovery.

Severe Obstructive Uropathy due to Mycobacterium avium Complex in an HIV Patient

Irene Nunuk, Carrie L. Phillips, Chad A. Zarse. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Tuberculosis is a well-known cause of genitourinary (GU) tract infection and obstructive uropathy, however, non-tuberculosis (non-TB) mycobacterium has not been commonly reported as a cause for kidney injury. Here, we present an HIV patient presenting with severe acute kidney injury (AKI) from bilateral obstructive uropathy that improved with treating Mycobacterium Avian Complex (MAC).

Case Description: 32yo with HIV on HAART therapy and CKD III (Cr 1.5 mg/dL six months prior) presented with back pain and AKI. Prior cystoscopy for gross hematuria months before showed erythematous bladder mucosa due to chronic active cystitis. Admission Cr was 4.2. Urinalysis detected large esterase with WBC and RBC >100/hpf despite two negative urine cultures. CT imaging revealed severe bilateral hydronephrosis with diffuse uroepithelial thickening. Cr worsened to 6.2, so bilateral nephrostomy tubes were placed. Chest CT showed small tree-in-bud nodularities in a bronchovascular distribution of the RLL consistent with granulomatous disease. Kidney biopsy specimen showed mild tubular atrophy and interstitial fibrosis with scant interstitial infiltrates of lymphocytes and no detectable acid-fast organisms. Renal cores sent for viral, bacterial, and fungal/AFB cultures were negative at 6 weeks. Of 4 serial early morning voided urine specimens sent for culture, only one grew MAC at week 8. She was treated with Azithromycin, Ethambutol, and Rifabutin. Nephrostomy tubes were removed without worsening obstruction. Six months post discharge Cr improved to 1.2.

Discussion: Ascending TB and non-TB GU infections are rare and difficult to diagnose. Susceptible patients presenting with kidney failure and sterile pyuria require thorough work up. Infections can cause obstructive uropathy via ascending tract inflammation and subsequent kidney injury. In our case, kidney biopsy and serial urine AFBs were necessary to identify a pathogen and rule out other HIV related renal pathology. Remarkably, only 1 of 4 serial urine AFBs were positive for non-Tb MAC, detectable only at week 8, demonstrating that physicians should remain vigilant to rule out infectious pathogens with close coordination with pathology and microbiology colleagues. Prompt treatment allowed for improvement of the inflammatory obstructive process and renal function.

PUB036

Can Quality Indicators in Continuous Renal Replacement Therapy (CRRT) Be Achieved in Middle Income Countries? A Comparison Between a Public and Private Hospital

Juan P. Gomez Villarreal,[1] Paola Borbolla,[2] Ricardo A. Garza Treviño,[1] Mara C. Olivo Gutierrez,[1] Elisa M. Guerrero Gonzalez,[1] Lilia M. Rizo Topete.[1,2] *[1]Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico; [2]Hospital Christus Muguerza Alta Especialidad, Monterrrey, Mexico.*

Background: As mentioned in ADQI 22nd, there are few studies that have been examined the Quality of Care (QoC) provided to patients with AKI that require RRT. As proposed by the experts, QoC is suboptimal, and substantial knowledge-to-care gaps that need to be addressed so that we can provide an adequate care and safety therapy for those who require.

Methods: We performed a dual - center retrospective analysis chart review of adults who required CRRT during the last year in the Hospital Universitario of Monterrey Dr. Jose Eleuterio Gonzalez (public hospital) and the Hospital Christus Muguerza Alta Especialidad (private hospital) in Nuevo Leon, Mexico. The quality assessments were: Patients prescribed dose, fluid management, filter life and small solute clearance which was compared to the ADQI QoC. Data was extracted from clinical records, all the patients that received CRRT in that period of time given were included; patients with incomplete clinical records were excluded. The analysis was performed with R version 4.0.

Results: A total of 22 patients were included, 11 in each cohort, overall results were as followed: 68.2% (15) were men, in 95.5% (21) patients the modality used was CVVHDF and 4.5% (1) received SCUF, the mean prescribed dose was 2450 ml/min, the ultrafiltrate was 75.5 ml/hr, the initial serum creatinine was 3.07 mg/dL, and in the day 2 the mean serum creatine was 2.18 mg/d the mean life of the filter was 64 hrs, in 59.1%. In the overall accomplishment of the goals, 77.3% accomplished the filter life > 60 hours, 68.2% accomplished goal for ultrafiltrate for at least 80%, and 90.9% accomplished the clearance goal. In comparison between hospitals, in the public hospital the filter life > than 60 hours was accomplished in 72.7% of the therapies, while in the private one in 81.8%, the ultrafiltrate goal was accomplished in 54.5% and 81.8% respectively, and the clearance goal in a 90.9% in both hospitals.

Conclusions: This comparison helped us to discern between what we can improve in both hospitals and what QoC and security measures we have accomplish already. It is important to mention that the quality indicators are not in order of importance as they should be and we must change this concept.

PUB037

Severe Hypercalcemia with Parathyroid Crisis Results in Acute Renal Failure Ending in Fatal Acute Respiratory Distress Syndrome (ARDS)

Towfiqul A. Chowdhury. *University of Rochester Medical Center, Rochester, NY.*

Introduction: We present a remarkable case of severe hypercalcemia resulting in a catastrophic outcome.

Case Description: A 52-year-old male with past medical history of obesity, hyperlipidemia, and BPH presented with fatigue, abdominal pain, constipation, and confusion. Medications included atorvastatin and tamsulosin. At the presentation vital signs and exam were unremarkable. Initial workup revealed: serum Ca 34.2, ionized Ca 7.0, Bun/Cr 58/6.60, iPTH 1180, PTHrP 2.2, and 1,25 Dihydroxy Vitamin D <0.5. CVVHDF with citrate regional anticoagulation was initiated. Imaging suggested an underlying parathyroid adenoma and/or carcinoma. Parathyroidectomy was recommended by Endocrine Surgery. On hospital day 2, the patient developed acute hypoxemic respiratory failure attributed to aspiration pneumonia. Chest X-ray revealed bilateral interstitial infiltrates. Echocardiogram showed normal LV function. The patient was diagnosed with ARDS and septic shock requiring multiple pressors. Due to persistent critical illness, the patient never became sufficiently stable to undergo parathyroidectomy, and the family opted for comfort measures.

Discussion: In addition to infectious causes, there are additional potential mechanisms for the development of ARDS. Severe hypercalcemia can lead to calciphylaxis affecting small and medium vessel walls, leading to intimal proliferation, fibrosis, and necrosis. It has been suggested that hypercalcemia may also produce sepsis-like syndrome and acute lung injury by increasing plasma nitrate/nitrite, free radicals, proinflammatory cytokines, and procalcitonin. There have only been 4 cases reported since 1974 linking hypercalcemia to ARDS. In some cases, autopsy findings revealed metastatic calcification of the alveolar surface and the destruction of the alveolar-capillary barrier in the setting of serum calcium levels > 20. Malignant hypercalcemia with multiorgan failure is known to increase mortality in the setting of CKD and CAD. Malignant hypercalcemia resulting in metastatic calcification is expected, but accompanying ARDS is seen less frequently. More study is needed to clarify a mechanistic link between malignant hypercalcemia and ARDS if one does indeed exist.

PUB038

Hypertriglyceridemia-Induced Acute Pancreatitis and Renal Failure Requiring Plasma Exchange and Continuous Veno-Venous Hemofiltration

Alina Cheema, Nataliia Dyatlova, Kiran Singh-Smith, Genaro E. Herrera Cano, Srimathi Manickaratnam. *UConn Health, Farmington, CT.*

Introduction: Severe hypertriglyceridemia is defined at a level of greater than 1000 mg/dL and accounts for 1-4% of patients with acute pancreatitis. Rapid lowering of triglyceride levels is achieved with plasmapheresis (PLEX), and when there is concomitant renal failure and shock, continuous veno-venous hemofiltration (CVVH) is the treatment of choice. We describe a case of hypertriglyceridemia-induced acute pancreatitis (HTG-AP) and renal failure where triglyceride levels were > 5300 mg/dL.

Case Description: A 48-year-old male with history of CKD stage 3a, T2DM, HTN and hyperlipidemia presented to the hospital with an altered mental status. Vital signs: T 100.9 °F, HR 111 beats/min, RR 29 breaths/min, and BP 73/56 mm/Hg. The patient was in acute respiratory distress requiring intubation. Complete blood count: WBC 11,300, hemoglobin 12.8 g/dL, hematocrit 37.3% and platelet count 69,000. Complete metabolic panel: creatinine 6.60 mg/dL, BUN 62 mg/dL, glucose 1,422 mg/dL, CO2 16 mEq/L, anion gap 30 mmol/L, serum osmolality 431 mOsm/kg, AST 267 U/L, ALT of 112 U/L, CK 5,542 U/L, lipase >3,000 U/L, and triglycerides >5,376 mg/dL. He was admitted to the ICU for HTG-AP and hyperosmolar hyperglycemic state requiring vasopressors and insulin infusion. Given his severe hypertriglyceridemia and acute kidney injury, PLEX was immediately initiated followed by CVVH. After two sessions of PLEX, triglyceride levels decreased to <500. Images were negative for necrotizing pancreatitis. However, the patient had worsening rhabdomyolysis with CK > 20,337 U/L, requiring CVVH for 7 days. Once hemodynamic and metabolic parameters improved, the patient was transitioned to intermittent dialysis. Serum creatinine had peaked at 7.4 mg/dL and was 3.9 mg/dL with GFR of 18 when he came off dialysis at the time of hospital discharge. On outpatient follow up, creatinine had further improved to 2.26 mg/dL.

Discussion: This is a complicated case of HTG-AP and renal failure that was highly responsive to both PLEX and CVVH, resulting in meaningful renal recovery. More than one observational study shows that the combination of PLEX and CVVH for the management of HTG-AP with organ dysfunction has better outcomes than CVVH alone. Our case supports the benefit of combination therapy in the setting of severe cases of HTG-AP.

PUB039

Combined Extracorporeal CO2 Removal and Renal Replacement Therapy in a Patient with Acute Respiratory Distress Syndrome (ARDS)

Marcelo D. Silveira,[1,2] Júlia B. Cabral,[1,2] Fernanda O. Coelho,[1,2] Paulo benigno P. Batista,[1,2] Rogerio Passos.[1,2] *[1]Hospital Alianca, Salvador, Brazil; [2]Hospital Sao Rafael, Salvador, Brazil.*

Introduction: In critically ill patients, concomitant lung and kidney damage can determine unfavorable outcomes. With recent technological advances, patients with acute respiratory distress syndrome (ARDS) and hypercapnia can benefit from extracorporeal

CO2 removal (ECCO2R). ECCO2R in ARDS allows lung-protective ventilation (LPV) with low tidal volumes. We describe the case of a patient with severe hypercapnia, threatening acidemia and acute kidney injury treated with ECCO2R membrane combined with continuous renal replacement therapy (CRRT).

Case Description: A 69-year-old man with a history of systemic arterial hypertension, diabetes and rheumatoid arthritis was admitted to the intensive care unit with severe pneumonia, septic shock and ARDS, also evolving with severe AKI. Chest tomography showing inflammatory infiltrate involving more than 80% of the parenchyma. Initial treatment involved ventilatory and circulatory support. Even after adjustments and ventilatory strategies, blood gas data showed persistent hypercapnia, PaCO2 reached 92 mmHg with resulting respiratory acidosis (arterial pH 7.03). He evolved with oliguria and severe hyperkalemia (K = 5.7 mEq/L) and was treated with an ECCO2R membrane inserted in series after a hemofilter in a CRRT platform. Nitric oxide and reverse prone were additional strategies used to rescue refractory hypoxemia. After 18 hours of therapy there was an improvement in hypercapenia with PaCO2 37mmHg and pH 7.41. After 72 hours maintaining metabolic balance, the use of ECCO2R was discontinued. The patient was extubated on the sixth day. He was discharged after 27 days of hospitalization without the need for supplemental oxygen and with normal renal function (sCr: 0.7mg/dl).

Discussion: We describe a case of success with the use of ECCO2R associated with CRRT in a critically ill patient. This combined therapy ensured an efficient metabolic balance and favored a substantial clearance of carbon dioxide, allowing LPV and greater lung protection, minimizing future.

PUB040

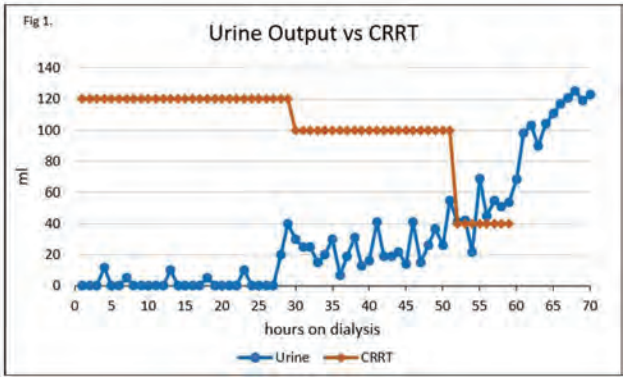
Continuous Urine Output Monitoring to Guide De-Escalation of Continuous Renal Replacement Therapy

Yacov Shacham,[1] Aliza D. Goldman.[2] *[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]RenalSense, Jerusalem, Israel.*

Introduction: Of heart failure patients with acute kidney injury (AKI), 20% progress to dialysis (AKI-D). We present a case of acute decompensated heart failure (ADHF) with severe AKI needing continuous renal replacement therapy (CRRT). Continuous electronic urine output (UO) monitoring was used to guide CRRT de-escalation until successful withdrawal.

Case Description: A 68y/o male was admitted to the cardiac intensive care unit with ADHF, recent myocardial infarction (MI), and severe left ventricular heart failure. Comorbidities: type 2 diabetes mellitus, hypertension, past MI, and chronic kidney disease. Baseline serum creatinine (SCr) was 1.98 mg/dl. On admission, a Foley catheter was inserted and connected to the RenalSense Clarity RMS electronic UO monitoring system. In the following 3 hours, he was non-responsive to 80 mg of IV furosemide. Furosemide dose was increased to 250 mg/day continuous IV, with severe oliguria (UO of 0.1-0.2 ml/kg/h) persisting over 24 hours. SCr increased to 2.8 mg/dl within 12 hours of admission and 3.9 mg/dl by 24 hours. CRRT was initiated due to AKI, fluid accumulation, and pulmonary congestion. Initial fluid removal was 120 ml/h. After 36 hours of CRRT, a gradual persistent increase of 0.2-0.4 ml/kg/h in UO was recorded. Consequently, CRRT fluid removal was reduced to 100 ml/h (Fig 1). Successful withdrawal of CRRT was followed by a polyuric stage over 36 hours gradually decreasing to 1-1.3 ml/kg/h until Foley removal four days later. Concurrently, SCr decreased to 1.82 mg/dl.

Discussion: Heart failure patients with AKI-D have increased risk of dialysis dependence and higher mortality. Optimal timing for CRRT initiation has been more widely studied than that for withdrawal. Predictive factors for successful CRRT cessation include UO, SCr, and time on CRRT. In this study, changes in UO guided CRRT fluid removal leading to gradual withdrawal of CRRT 60 hours after initiation, and UO increase to 120 ml/h. This case study suggests using continuous electronic UO monitoring to guide de-escalation from CRRT.



PUB041

Development of Risk Model to Predict the Cause of Death due to Kidney Disease: A Need of the Hour

Prof Narinder P. Singh,[1] Dinesh Khullar,[1] Anish K. Gupta,[1] Tripti Khanna,[2] Gurleen Kaur,[3] Neeru P Aggarwal.[4] *[1]Max Super Speciality Hospital, Saket, Delhi, Delhi, India; [2]Indian Council of Medical Research, Delhi, India; [3]Southwest Georgia Medical Center, Georgia, GA; [4]Max Super Speciality Hospital Vaishali, Ghaziabad, India.*

Background: Death attributable to a particular condition is a major quantifier of disease burden and any error in this data could lead to significant health-care inequities. We hypothesized that cross-comparison of COD (cause of death) due to kidney disease in death certificates with chart review of hospital records would highlight this error. We aimed at developing a risk prediction score for accurately documenting COD due to kidney disease and to validate this model internally.

Methods: A retrospective chart review was conducted in a tertiary care hospital on randomly selected death cases from medical ICUs. A risk prediction model for COD attributable to renal disease was developed using multivariable logistic regression. Discrimination and calibration measures for the model were calculated and model presentation was done using an e-calculator.

Results: A total of 365 patient charts were scrutinized. Our study findings showed that there was underreporting of COD attributed to kidney disease in the death certificate after verification of hospital source documents. Clinical characteristics that accurately predicted COD due to kidney disease in our model included documentation of- Oliguria, and hemodialysis, followed by sepsis, dehydration or volume depletion, cardiovascular disease, circulatory shock, anemia, and advanced age. The final model had good discriminant scores/c-statistics of 0.87 for threshold probability >50% and good calibration by the goodness of fit test statistic 4.571(df=8,p=0.8022).

Conclusions: There was under-reporting of COD due to kidney disease in death certification. A validated risk prediction model was developed for accurately documenting COD due to kidney disease. Future research includes multi-centric external validation of the risk model.

An Unusual Presentation of Atypical Hemolytic Uremic Syndrome: Acute Disease Without Platelet Consumption

Gianluigi Ardissino, Thomas Ria, Maria Cristina Mancuso, Luigi Porcaro, Massimo Cugno. *Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a thrombotic microangiopathy (TMA) in which platelet consumption is a key diagnostic element, together with hemolysis and kidney damage.

Case Description: Herein, we described a peculiar case of aHUS due to complement factor H mutation (c.238T>A/p.Cys80Ser) that repeatedly occurred without evidence of platelet consumption. The patient was 39 years-old when she first experienced aHUS following uneventful pregnancy and delivery. The diagnosis was confirmed by renal biopsy and the patient was successfully treated with eculizumab, discontinued after full recovery. Five years later, without an evident trigger, the patient experienced an aHUS relapse with AKI, hemolytic anemia but still no evidence of platelet consumption. Eculizumab treatment was re-started and remission was obtained with full recovery of renal function. Laboratory data are reported in the table. The patient has always suffered from frequent mild bleeding episodes (epistaxis, gingival bleeding, menorrhagia, ecchymosis following mild trauma). Platelet functional tests (aggregation, secretion, nucleotide and serotonin) only showed a granule secretion and an intra-platelet serotonin at the lower normal limit. Platelet procoagulant activity is being investigated.

Discussion: The episodes of aHUS experienced by this patient were all characterized by a mild course and the patient never required dialysis, suggesting a critical role of platelet consumption in determining the severity of the disease. Our data suggest future studies to evaluate a possible role of antiplatelet therapy in the prophylaxis of patients at risk of aHUS.

A Rare Case of Vancomycin-Induced Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) Syndrome, Eosinophilic Pneumonitis, and Steroid-Resistant Acute Interstitial Nephritis Requiring Additional Immunosuppression: A Case Report

Noah J. Poznanski, Bernard G. Jaar, Samir C. Gautam. *Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) syndrome is a severe hypersensitivity reaction characterized by a skin rash, fever, hematological abnormalities, and multiorgan involvement. Acute Interstitial Nephritis (AIN) can occur in 10%-30% of cases. We describe the case of a patient with DRESS syndrome due to vancomycin, with widespread rash, eosinophilic pneumonitis, and steroid-resistant AIN, leading to successful resolution with immunosuppression.

Case Description: A 73-year-old female with a history of breast cancer on exemestane, GERD, and hypothyroidism who presented to the emergency department with a pruritic, erythematous rash spreading from the chest to the extremities and face over two days. She had a vertebral fusion complicated with MRSA-vertebral osteomyelitis, treated with prolonged IV vancomycin. Physical examination was unremarkable except for diffuse erythematous macules and papules on the trunk and extremities. Laboratory data showed peripheral eosinophilia, elevated liver enzymes, and acute kidney injury with an initial creatinine 0.9 mg/dL. Her clinical condition deteriorated despite high-dose prednisone, with new onset hypoxemic respiratory failure, pleural effusions, and worsening kidney function (peak serum creatinine 2.9 mg/dL). A skin biopsy confirmed DRESS syndrome, and subsequent evaluations revealed eosinophilic pneumonitis, with a kidney biopsy consistent with severe acute interstitial nephritis. Given the steroid-resistant AIN and pulmonary involvement, cyclosporine, and mycophenolate mofetil were initiated. Her overall clinical condition gradually improved with serum creatinine down to 1.4 mg/dL.

Discussion: This case emphasizes the importance of promptly diagnosing AIN through renal biopsy in patients with worsening acute kidney injury despite discontinuation of the offending agent. Aggressive follow-up and consideration of additional immunosuppressive measures may be necessary if steroids fail. Although the specific impact of each medication is difficult to discern, mycophenolate has shown promise as a therapeutic option for steroid-resistant AIN, warranting further investigation.

PUB044

Shiga Toxin-Directed Complement-Mediated Hemolytic Uremic Syndrome Treated with Eculizumab

Parth Kumar, Man Kit Michael Siu, Ekamol Tantisattamo, Antoney J. Ferrey. *University of California Irvine, Irvine, CA.*

Introduction: Hemolytic uremic syndrome (HUS) has classically been used to refer to Thrombotic Microangiopathies that occur with acute kidney injury. The terminology has evolved and is now typically divided into ST-HUS (formerly diarrhea associated HUS) and CM-TMA (formerly atypical HUS). ST infections are typically acquired through consumption of contaminated food or water, or through contact with infected animals or their environment. Kidney injury occurs as a result of the shiga toxin causing native cells to undergo apoptosis. Shiga toxin is also prothrombotic through intracellular pathways contributing to the injury of normal cells. CM-TMA formerly referred to as atypical HUS occurs when there is unrestrained activation of the alternative pathway of complement causing injury of normal cells.

Case Description: We report a case of a 43-year-old female that presented with 3 days of nausea, vomiting, epigastric pain and bloody diarrhea. Family reported patient had eaten undercooked boiled eggs. Lab work notable for an anion gap metabolic acidosis with concomitant non anion gap metabolic acidosis in setting of mild lactic acidosis, acute kidney injury, acute bloody diarrhea and thrombocytopenia. Hospital course complicated by worsening renal function and mental status requiring initiation of dialysis. HUS secondary to shiga toxin and other thrombotic microangiopathy (TMA) were considered. ADAMTS-13 was 29% and O157:H7 grew on chromogenic agar with testing positive for Shiga toxin. Case discussed among transfusion medicine and nephrology team; patient was managed as atypical HUS with monoclonal anti-C5 inhibitor, Eculizumab. The TMA panel equivocal, but showed heterozygous missense mutation on PLG, three polymorphisms on CFH gene, and negative for C5 polymorphisms. Patient improved and two weeks later, in clinic, patient noted to have complete renal recovery.

Discussion: This case highlights the importance of considering anticomplement therapy for select cases of ST-HUS. An interesting point was the patient's TMA genetic profile and how it helped direct her care. Our case illustrates the difficulty definitive diagnosis, but the importance for early consideration of aHUS in patients presenting with TMA. More importantly, we highlight that near-normal renal recovery may be attained with eculizumab in adults even after a dependence on dialysis.

PUB045

A Curious Case of ANCA Glomerulonephritis and Membranous Nephropathy: A Rare Double Hit

Melissa Baker, Alvin G. Kwon, Yuliya Sharakova. *Cleveland Clinic, Cleveland, OH.*

Introduction: Membranous glomerulonephritis (MGN) is typically diagnosed in patients with preserved renal function. Hematuria is common in these cases. Subepithelial immune complex deposits are the pathologic finding on biopsy and result in spike formation of the glomerular basement membrane. Secondary causes of MGN, about 25% of cases, can be attributed to infection, malignancy as well as several drugs. However, ANCA-associated necrotizing and crescentic glomerulonephritis (GN) appears more rapidly progressive than MGN and can have active urine sediment with RBC casts. Rarely are these two conditions seen together.

Case Description: Patient is a 62-year-old man with HTN, atrial fibrillation and COPD who presented with shortness of breath. During the initial workup he was found to have a large pulmonary mass with liver metastasis as well as renal failure with a creatinine of 7 mg/dL. This patient had no known baseline renal function. He was subsequently started on dialysis. Urinalysis would show proteinuria, hematuria and several granular casts, a protein to creatinine ratio would result 7.3 mg/mg. Serologies were obtained and a positive p-ANCA and MPO >8.0 were found. A renal biopsy was done on the 5th day of admission and confirmed ANCA-associated necrotizing and crescentic GN as well as MGN. The overwhelming finding on the biopsy was the necrotizing crescentic GN. Staining for PLA2R, Exostosin and NELL 1 was negative. Pulse dose steroids were given for 3 days as well as oral cyclophosphamide initially. A biopsy of the liver metastasis would reveal that this patient had metastatic small cell lung cancer. In this setting, the use of immunosuppressive treatments would pose a significant challenge. Ultimately, the patient chose to go home and declined any further treatments.

Discussion: Rarely, ANCA-associated GN and MGN are seen together. In this case it was thought to be in the setting of two distinct disease processes. The MGN was thought to be secondary to the recently diagnosed malignancy with the ANCA-GN being a separate entity. Renal prognosis in this situation was guarded as treatment of ANCA-GN is very challenging in the setting of malignancy with associated secondary MGN. It is important to be aware of this possible coexistence when ANCA-GN is associated with nephrotic range proteinuria.

PUB046

A Rare Case of ANCA-Mediated Acute Interstitial Nephritis Without Glomerulonephritis

Luis B. Caraballo, Hima B. Doppalapudi, Kirti Basil, Vijay K. Vanguri. *University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Acute interstitial nephritis (AIN) is characterized by an inflammatory infiltrate in the kidney interstitium which is most commonly caused by drugs, with less common contributors being infections and systemic diseases, and generally leading to acute kidney injury. Here we present a case of an 80-year-old female patient with AIN thought to be caused by non-myeloperoxidase (MPO), non-proteinase-3 (PR-3) antineutrophil cytoplasmic antibody (ANCA) without glomerular involvement.

Case Description: An 80-year-old female was referred to the renal clinic with acute kidney injury and a one-month history of worsening fatigue, nausea, and poor appetite. Her medical history was notable for resistant hypertension, maintained in seven anti-hypertensives for over 40 years. Her creatinine was 4.2 mg/dL, with a baseline creatinine of 0.7 mg/dL about six months prior to presentation. Blood pressure was 132/68 mm Hg. Urine sediment showed several WBCs and WBC casts with no evidence of infection. She had minimal proteinuria and serologic work-up revealed positive c-ANCA with titers >1:640, but negative PR3 and MPO antibodies. A renal biopsy showed markedly active tubulointerstitial nephritis, predominantly composed of lymphocytes and plasma cells and minimal eosinophils, along with mild granular immune complex deposition (1+ IgG, IgA, and C1q) in some tubular basement membranes and interstitium suggestive of an autoimmune etiology. All 33 glomeruli were unremarkable, with no crescents, immune complexes, or inflammation. She was treated with prednisone 1 mg/kg with a slow taper, and her creatinine continued to improve drastically along with a concurrent decline in c-ANCA titers.

Discussion: ANCA-associated vasculitides (AAV) are a group of disorders that typically cause pauci-immune glomerulonephritis, including granulomatosis with polyangiitis, microscopic polyangiitis, renal-limited vasculitis, and eosinophilic granulomatosis with polyangiitis. ANCA-associated AIN especially without glomerular involvement is rarely seen. Moreover, non-MPO and non-PR3 ANCAs are infrequent and could be pathologic in nature. Our case is suggestive of non-PR3 and non-MPO ANCA-associated AIN without glomerular involvement, which improved drastically with corticosteroid therapy. In cases of AIN without obvious causative drugs, serological work-up including ANCA screen should be considered.

PUB047

AKI and Spontaneous Rupture of the Urinary Collecting System

Alaaeldin Mustafa, Muhammad U. Jahngir, Sumithra Nalla, Jean Lee. *Temple University, Philadelphia, PA.*

Introduction: Obstructive uropathy is an uncommon cause of AKI and usually associated with bladder neck dysfunction. Rupture of the renal calyx with bilateral(B/L) hydronephrosis in the absence of bladder neck dysfunction is even rare. We are reporting a case of bilateral hydronephrosis causing rupture of left collecting system.

Case Description: An 81-year-old man was admitted with altered mental status, hyperkalemia and metabolic acidosis due to AKI with creatinine of 16mg/dl (BL 1mg/dl). Several weeks prior to admission while traveling abroad, he had developed left flank pain, painful urination and hematuria. CT scan abdomen revealed B/L hydronephrosis and a collection around the left kidney consistent with calyceal rupture of the renal pelvis. Prostatomegaly was observed but the bladder was not distended. Despite the insertion of a Foley catheter, the patient remained anuric and required hemodialysis for altered mental status and severe metabolic acidosis. He then had a percutaneous nephrostomy tube placed in right kidney and a drainage tube into the left sided collection, which resulted in rapid improvement of renal function. Cystoscopy revealed a necrotic partially calcified mass which engulfed the right lateral wall of the bladder, extended to the bladder neck, and was accompanied by a few small satellite lesions on the posterior bladder wall with distortion of the trigone region of bladder. The bladder mass was revealed to be a papillary urothelial carcinoma. He was sent home with bilateral ureteral stents and a percutaneous drain on the left. The patient's SCr down trended to a nadir of 0.91mg/dl prior to discharge.

Discussion: Spontaneous rupture of the collecting system is rare and is typically unilateral with the most plausible mechanism being, gradual increase of intraluminal pressures up to 75mmHg. About half of the cases of spontaneous urinary extravasation are caused by ureteral stones, while occurrences related to tumors are rare. Interestingly, when extravasation is associated with a tumor, it tends to occur more frequently on the left side rather than the right side. The exact reason for this asymmetry is not known, but it is hypothesized that the direct extension of tumor cells may be easier on the left side, creating weak points along the path of extension, leading to leakage and rupture.

PUB048

A Case of Terbinafine-Associated Rhabdomyolysis and Drug-Induced Liver Injury (DILI) That Progressed to Acute Renal and Liver Failure

Gabriela S. Mosquera Cordero. *Novant Health New Hanover Regional Medical Center, Wilmington, NC.*

Introduction: Terbinafine is commonly prescribed for the treatment of onychomycosis. Has been associated with acute hepatic injury and rarely associated with rhabdomyolysis, acute renal failure (ARF) and liver failure (LF). Here we present a case of a patient presenting with general muscle weakness with elevated CK, abnormal renal and hepatic function. Notably, the only new medication reported was terbinafine 3 weeks prior to hospital admission.

Case Description: A 72 year-old female presented to the hospital for worsening of general muscle weakness. Patient completed treatment for onychomycosis with terbinafine 3 weeks prior. The patient denied any other new medications for the past few years. Lower extremity weakness was initially attributed to worsening of spinal stenosis. Lumbosacral MRI was performed, and it showed progression of spinal stenosis but no cord compression. Neurosurgery consult advised against surgical intervention. Chemistry was relevant for CK >9000; Cr 5.78; BUN 117; with a mixed hepatocellular and cholestatic pattern. Autoimmune and infectious etiology were investigated but all were negative. USG and MRI showed CBD dilation correlated with age and post cholecystectomy status. Patient's CK continued upward with minimal urine output. Patient rapidly decompensated, requiring transfer to ICU, and dialysis. Unfortunately, the patient passed away hours later.

Discussion: Terbinafine is a common antifungal drug used for onychomycosis that may cause hepatic or renal toxicity. The side effects are usually self-limiting, but can rarely progress to rhabdomyolysis, ARF, DILI and LF. Few cases of rhabdomyolysis and ARF associated with Terbinafine have been reported, and even less cases were associated with DILI leading to LF. There are limitations with the definitive diagnosis due the patient passed away before perfforming liver or renal biopsy. Treatment primarily consists of stopping the causative agent and NAC for DILI, but some cases with liver failure will require liver transplantation, and dialysis for worsening of renal failure. There is a lack of guidelines and cases associating Terbinafine with rhabdomyolysis, ARF, or LF. Nevertheless, physicians need to be aware and carefully monitor patients when prescribing this medication, especially with prior history of chronic renal or liver conditions or any chemistry abnormalities related to its use.

PUB049

Calciphylaxis in a Patient with Lupus Nephritis and Recent AKI

Zohreh Gholizadeh Ghozloujeh, Roy O. Mathew, Amir Abdi Pour, Sayna Norouzi. *Loma Linda University Medical Center, Loma Linda, CA.*

Introduction: Calciphylaxis is a rare and severe disease characterized by calcification, fibrosis, and thrombosis of small blood vessels. While it primarily affects patients with end-stage renal disease (ESRD) on dialysis, limited cases of calciphylaxis in patients with acute kidney injury (AKI) and lupus have been reported.

Case Description: This case report describes the occurrence of calciphylaxis in a 35-year-old Hispanic female recently diagnosed with lupus nephritis class IV and acute kidney injury requiring dialysis for two months. AKI was resolved, and the patient was off dialysis when she presented with new-onset skin lesions on her thighs, which progressively enlarged and were associated with pain and itching. Physical examination revealed stellate-shaped purpuric patches and plaques on the thighs, which were painful, firm, and indurated, with focal overlying necrosis. The serum phosphate was 1.4 mmol/L, and the parathyroid hormone was 177 pg/mL. Dermatology was consulted. A CT scan revealed mottled foci of calcifications in the pelvic area and subcutaneous soft tissues. Skin biopsy was suggestive of possible CUA with dermal necrosis and dilated blood vessels. Sodium thiosulfate was initiated with mild improvement in lesion appearance and symptoms.

Discussion: This case report highlights the importance of the possibility of CUA in the setting of lupus nephritis. It also emphasizes the importance of a multidisciplinary approach to optimize the management of calciphylaxis.

PUB050

Prdx1 Aggravates Hypoxia-Induced Renal Injury

Yuanyuan Han, Zhangzhe Peng. *Xiangya Hospital Central South University, Changsha, China.*

Background: Hypoxia refers to a condition in which oxygen is limited. Hypoxia can trigger a renal injury response and may stimulate inflammation of proximal tubular cells by damage-associated molecular patterns (DAMPs). Extracellular Prdx1 can play the role of DMAPs by activating the pro-inflammatory response. Previous studies have demonstrated that Prdx1-mediated activation of TLR4/NF-κB contributes to neuroinflammatory responses in intracerebral hemorrhage and acute liver injury. However, the role of extracellular Prxd1 after hypoxia-induced renal injury has not been clarified.

Methods: 1.A 3d and 7d hypoxia model was established in wild-type mice to observe renal function, kidney injury and Prdx1 expression. 2.Hypoxia model was established in Prdx1 knockout mice, and renal function, kidney injury, inflammation and MAPK/NF-κB expression were observed.

Results: 1.Hypoxia can induce kidney injury in mice, and Prdx1 content in serum and kidney tissue increases in the mice model of hypoxia for 3d and 7d. 2.After Prdx1 knockout, hypoxia-induced kidney injury, inflammation and phosphorylation of MAPK and IκB of mice were alleviated.

Conclusions: 1.In the mouse model of hypoxia, the expression of Prdx1 in serum and kidney is increased; 2.Circulating Prdx1 aggravates hypoxia-induced kidney injury by activating MAPK/NF-κB mediated inflammation.

Lymphadenopathy with AKI

Ramandeep Kaur, Branavan V. Ragunanthan, Jason R. Pettus, Brian D. Remillard. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Immunoglobulin G4-related disease (IgG4-RD) can present with different manifestations simultaneously. We present a case of bilateral inguinal lymphadenopathy with AKI found to have IgG4-RD.

Case Description: A 77-year-old female with history of bladder cancer s/p resection and urostomy, DM-2, COPD, HTN and HLD presented with 2 week history of right sided flank pain after being treated for urinary tract infection. She endorsed poor oral intake, shortness of breath and persistent abdominal pain. On physical examination, bilateral inguinal lymphadenopathy was found. In the laboratory evaluation, serum creatinine was 2.57 mg/dL (reference range 0.8-1.5 mg/dL). Two months prior, it was 0.83 mg/dL. Immunological data revealed elevated IgG level at 3,994 mg/dL (reference range 700-1000 mg/dL). IgG4 level was 773.2 mg/dL (reference range 3.9-86.4 mg/dL). C3 and C4 complements were low at 32 mg/dL (reference range 90-180 mg/dL) and < 2 mg/dL (reference range 10-40 mg/dL). Computed Tomography showed mild pelvocaliectasis and ureterectasis. The biopsy of inguinal lymph node showed plasma cells with storiform pattern. A renal biopsy showed marked plasma cell rich interstitial chronic inflammation with a high fraction of IgG4-restricted plasma cells, proliferative fibrosis, and both

tubulointerstitial and glomerular immune complex deposits, consistent with IgG4-related kidney disease. The patient was treated with pulse steroids followed by steroid taper and IV Rituximab. Two months later, her IgG4 level has decreased. The creatinine has trended down to 1.17 mg/dL.

Discussion: We present a case of IgG4-RD diagnosed with renal biopsy with response to steroids and Rituximab.

PUB052

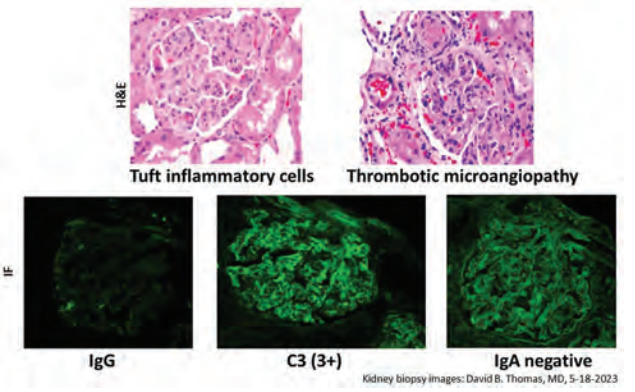
Atypical Hemolytic Uremic Syndrome Induced by Inflammatory Bowel Disease

Fausto R. Cabezas, Charlie Spell, Sandeep R. Sasidharan, Sonalika Agarwal, Mary C. Mallappallil, Isha Puri. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a congenital or acquired dysregulation of the complement alternative pathway that leads to thrombotic microangiopathy (TMA) and acute kidney injury (AKI). The prevalence of aHUS ranges from 2 to 10 cases per million. There have been few reports of aHUS associated with Inflammatory bowel disease (IBD). We present a case of a young man with IBD and biopsy proven TMA associated AKI.

Case Description: A 26-year-old male presented with 4 weeks of hematochezia. Laboratory data showed severe hemolytic anemia (hemoglobin 2.9 gr/L, schistocytes on smear; LDH 1,415 U/L, haptoglobin <10 mg/dL, Coombs test), leukocytosis (52.87 k/uL), thrombocytopenia (107 k/uL); severe AKI (SCr 8.32 mg/dL from previous normal eGFR), urinalysis showed 10 WBCs/HPF, RBC 9/HPF, protein 100 mg/dL. Kidney ultrasound was unrevealing. ADAMTS-13 activity was 43% with decreased complement levels (C3 40, C4 25, CH50 17). Negative Shiga toxin. Sigmoidoscopy showed diffuse mucosa inflammation throughout rectum, descending and transverse colon. Biopsies demonstrated chronic colitis. He received multiple transfusions and empiric antibiotics with no improvement. Intravenous methylprednisolone (0.5 mg/kg/day) was started. AKI started to improve before complement blockade therapy with Eculizumab. Kidney biopsy showed acute TMA with immune mediated C3 dominant diffuse proliferative glomerulonephritis (figures). Genetic panel testing for aHUS associated mutations showed no pathological variants.

Discussion: This patient presented with one month of gastrointestinal symptoms preceding the AKI and hemolytic anemia. Overlap of symptoms and laboratory markers pose a challenge when identifying aHUS. In contrast to our case, previous reports have shown remission of AKI and chronic relapsing IBD only after Eculizumab is started. This is a rare case of IBD induced aHUS which responded to a course of steroids and Eculizimab.



PUB053

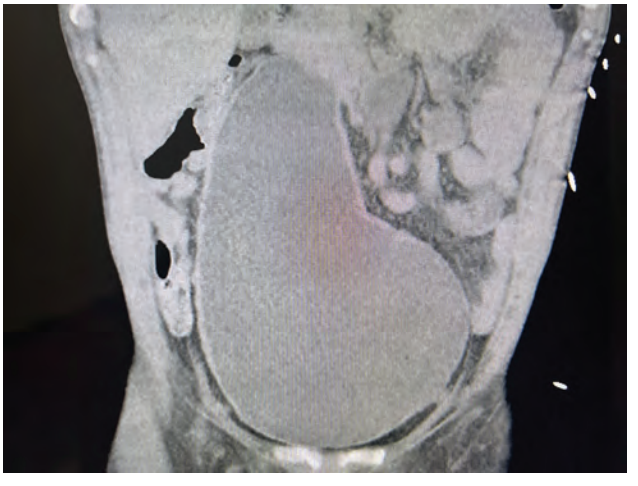
Giant Urinary Bladder Causing Massive Hydronephrosis

Esosa U. Ukponmwan. *Michigan State University, East Lansing, MI.*

Introduction: Obstructive uropathy is caused by a structural or functional impairment in urinary flow. It is a potentially reversible cause of acute and chronic kidney disease, accounting for 10 percent of acute and chronic kidney disease.

Case Description: A 58-year-old man presented with fatigue, shortness of breath and dyspnea on exertion for eight months, worse over the previous week. He also complained of urinary frequency, urgency, hesitancy, feeling of incomplete urinary bladder emptying, terminal dribbling, abdominal pain and swelling. He was pale, dyspneic, diaphoretic and in respiratory distress. Rales present bilaterally, heart sounds were normal. Abdomen was tender and distended. No pedal edema. He had an elevated blood urea nitrogen of 126mg/dl and creatinine of 9.24mg/dl, high anion gap metabolic acidosis, hyperkalemia and hyperphosphatemia. CT-scan chest, abdomen and pelvis revealed pulmonary edema, severe bilateral hydronephrosis and hydroureter down to the urinary bladder. Marked distention of the urinary bladder causing bowel obstruction. Cortical atrophy of the kidneys suggesting chronic obstruction. Foley catheter was placed with 3500mls of urine drained. Hemodialysis was started due to symptoms of pulmonary edema and uremia. Overall clinical status improved. He was placed on long-term foley catheter and tamsulosin started, with nephrology and urology follow up.

Discussion: Early recognition of obstructive uropathy is important in management of acute and chronic kidney disease. There is an inverse relationship between duration of obstruction and recovery.



Giant urinary bladder

Massive hydronephrosis

PUB054

Long-Term Safety/Outcome of a Novel Half-and-Half (Darbepoetin/ Epoetin) Combination Therapy in Hemodialysis Patients: A Comparison with Epoetin-Monotherapy Period

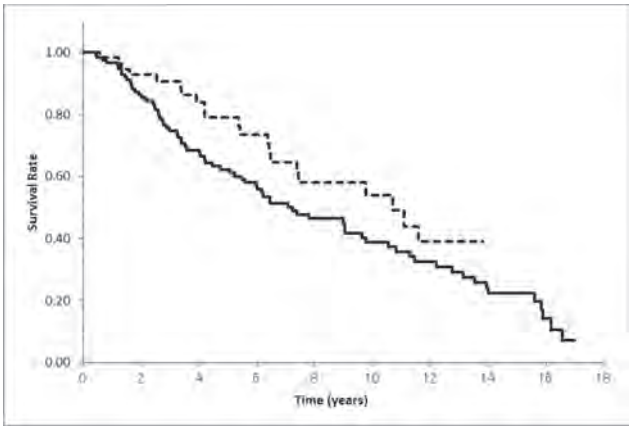
Kazumasa Shimamatsu, Yoshihiro Mimura. *Shimamatsu Naika Iin, Chikushino, Japan.*

Background: Long-acting erythropoiesis-stimulating agent (ESA), darbepoetin (DA) has a longer terminal half-life and a reduced dose frequency than short-acting epoetin (EPO). However, DA might be associated with increased mortality. To lower mortality risk concerned, we reported a novel *half-and-half* (DA/EPO) combination therapy consisting of a stable dose of DA occasionally assisted by EPO having resulted in reduced hemoglobin fluctuation, reduced ESA doses, and lower costs. Long-term safety/ outcome of the *half-and-half* therapy was evaluated.

Methods: All the 280 patients on maintenance hemodialysis (HD) during 31 years are subject to this study. Out of 280 patients 189 belonged to EPO monotherapy period (EPO period), and 91 belonged DA/EPO combination therapy period (*half-and-half* period). For retrospective analysis, we selected 120 patients who had been transferred to our clinic within one year after the initiation of HD in EPO period and 64 patients in *half-and-half* period. The Kaplan-Meier survival curve of the *half-and-half* period was compared with that of the EPO period.

Results: The age of the HD patients in *half-and-half* period was significantly older than that of the HD patients in EPO period (66.6±11.8 vs. 60.1±14.9 yrs, p<.005). The gender, HD vintages at the time of transference to the clinic and original renal diseases were not significantly different between the EPO period and *the half-and-half* period. The Kaplan-Meier survival curve of the *half-and-half* period was significantly superior to that of the EPO period despite the older ages (Figure).

Conclusions: A novel *half-and-half* therapy may be safely feasible with rather better survival and also might be a way to avoid a potential risk on mortality of long-acting ESAs.



Kaplan-Meier survival curves of EPO period (solid line) and *half-and-half* period (dotted line). There is significant difference between the two survival curves (generalized Wilcoxon test, p<0.05).

Therapeutic Effect of Originator Erythropoiesis Stimulating Agents (ESAs) vs. Biosimilar ESAs on Hemoglobin Level in Hemodialysis Patients: A Single-Center Study

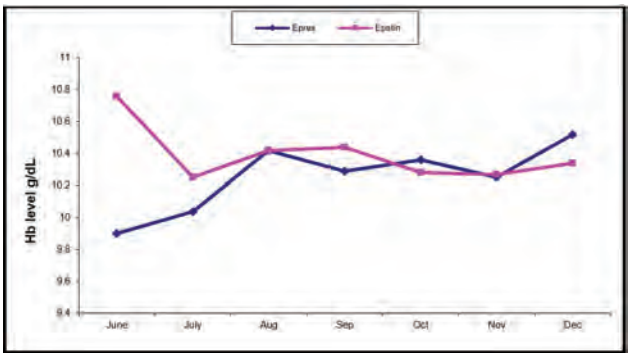
Ahmed Emara,[1,2] Osama I. Azab,[3,2] Goodluck R. Maro,[2] Ahmed Y. Ali.[4,2]
[1]Ain Shams University Faculty of Medicine, Cairo, Egypt; [2]Armed Forces College of Medicine, Cairo, Egypt; [3]Maadi Military Hospital, Cairo, Egypt; [4]Cairo University Kasr Alainy Faculty of Medicine, Cairo, Egypt.

Background: The use of ESAs and IV iron is the main line of treatment of renal anemia. There are few studies done to compare efficacy & cost benifit of originator vs. biosimilar ESAs. The aim of this study was to compare the therapeutic effect of originator ESA (Eprex®) vs biosimilar (Epoetin®) on mainataing Hb to the target level among ESRD patients on Hemodialysis (HD).

Methods: Prospective cohort study involved 81 prevalent HD patients in Maadi Military Hospital, Cairo. patients were randomised into two cohorts, Originator ESA (Eprex®) (27 subjects) and biosimilar Epoetin® (54 subjects). Baseline data including Hb, ESAs (dose & cost) and dialysis specifications and adequacy parameters were recorded at the time of enrollment, then monthly for 6 months for all patients. Iron studies were done at baseline & every 3 months.

Results: A total of 81 patients completed the study. both groups were age & gender matched. Eprex group (27 subjects) had more males (18 '66.7%') and Epoetin group (54 subjects) had more female (29 ' 3.7%') *(p = 0.083).* Baseline Hb was *lower* in Eprex vs. Epotin group (9.9±1.3 g/dL vs. 10.8±1.3g/dL respectively) *(p = 0.006).* The absolute Hb change relative to baseline for six months of follow up in Eprex vs. Epotin was ranging between 0.1 – 0.5g/dL vs. 0.4 – 0.1 g/dL respectively *(p = 0.007).* The median dose used in Eprex vs. Epotin were comparable, ranged between, 6-10 vs. 4-8 ampules per month, respectively *(p >0.05).* in both groups, no significant difference in the % of patients attained target Hb in Eprex vs. Epotin (66.7% vs. 61.1% respectively *"p >0.05").* The total cost in the 6 months study period was *significantly lower* in Epotin vs Eprex group, it ranged between 472-630 LE vs 2131-2648 LE respectively *(p =* <0.001).

Conclusions: Biosimilar epoetin® showed therapeutic equivalence with lower cost compared to originator drug (Eprex®) in maintaining Hb to target level in ESRD patients on HD.



Trend of mean Hb level in both groups over the study (6 months)

PUB056

Exploring the Potential of ChatGPT as an Artificial Intelligence (AI)-Powered Resource for Patient Education on a Renal Diet

Ahmad A. Qarajeh,[1] Supawit Tangpanithandee,[2] Pajaree Krisanapan,[3] Oscar A. Garcia Valencia,[2] Maria Lourdes Gonzalez Suarez,[2] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[2] *[1]The University of Jordan, Amman, Jordan; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Thammasat University Hospital, Khlong Nueng, Thailand.*

Background: Patients with chronic kidney disease (CKD) require a customized renal diet to avoid complications such as hyperkalemia and hyperphosphatemia. However, managing the nutrition of CKD patients requires careful time-consuming analysis of food composition. ChatGPT, an AI language model, has the potential to serve as a patient education resource.

Methods: To assess ChatGPT's accuracy in determining the potassium and phosphate content of food items, we presented 240 food items to ChatGPT in two separate sessions with a two-week interval between them. We selected the food items based on their potassium (149 items) and phosphate (91 items) content using the Mayo Clinic's renal diet book for patients with CKD. We asked ChatGPT to categorize each food item as having high or low potassium and high phosphate content. We compared the results with those from the Mayo Clinic Renal Diet book and computed the overall concordance to determine ChatGPT's accuracy and reliability.

Results: Our results showed that ChatGPT demonstrated moderate to high accuracy in identifying food items with high or low potassium and phosphate content in a renal diet. ChatGPT correctly classified 98 out of 149 (66%) food items as having high or low potassium content. Among the 81 food items with high potassium content, ChatGPT correctly identified 72 (89%), while it classified 26/68 (38%) of low potassium foods correctly. ChatGPT correctly classified 77 (85%) out of the 91 food items with high phosphate content. The concordance between the two ChatGPT sessions was 121/149

(81%) for potassium-containing food items, with 54/68 (79%) and 67/81 (83%) for low and high potassium food items, respectively. The concordance between the two ChatGPT sessions was 82/91 (90%) for phosphate-containing food items.

Conclusions: ChatGPT exhibited moderate to high accuracy in identifying food items with high or low potassium and phosphate content in a renal diet. ChatGPT's precision was higher for identifying food items with high potassium or phosphate content than those with low content. The overall concordance between two ChatGPT sessions was high, indicating ChatGPT's consistency in producing results. Further research is required to optimize its performance and maximize its potential as a clinical tool.

PUB057

Exploring the Use of Artificial Intelligence (AI) and Machine Learning in Nephrology Research: A Bibliometric Analysis

Pajaree Krisanapan,[1,2] Yuh-Shan Ho,[3] Tibor Fulop,[4,5] Wisit Cheungpasitporn.[1]
[1]Mayo Clinic Minnesota, Rochester, MN; [2]Thammasat University Hospital, Khlong Nueng, Thailand; [3]Asia University, Taichung, Taiwan; [4]Medical Services, Ralph H. Johnson VA Medical Center, Charleston, SC; [5]Medical University of South Carolina, Charleston, SC.

Background: Artificial intelligence (AI) and machine learning (ML) have increasingly been integrated into the field of nephrology in recent years. This study aimed to identify the most productive authors, institutions, and countries in this field, examine publication trends and patterns, and investigate the impact of collaboration on citations.

Methods: The study utilized the Science Citation Index Expanded (SCI-EXPANDED) of Clarivate Analytics Web of Science Core Collection to search for AI and machine learning publications related to nephrology from 1992 to 2021. The authors used quotation marks and Boolean operator "or" to search for keywords in the title, abstract, author keywords, and Keywords Plus. The 'front page' filter was applied to exclude non-research articles. A total of 5,425 documents were identified and analyzed.

Results: The results showed that articles represent 75% of the analyzed documents, with an average authorship ratio of 7.4 and an average number of citations per publication in 2021 of 18. English articles had a higher citation rate than non-English articles. The USA was preeminent in all publication indicators, followed by China (**Figure**). Collaborative research was found to enhance citations in the field.

Conclusions: This study provides a comprehensive analysis of the use of AI and ML in nephrology research publications from 1992 to 2021. Collaborative research was found to be important in advancing the field, and the study highlights research foci and frequently used author keywords. These results can guide researchers and practitioners in identifying key areas of research and advancing the use of AI and ML in nephrology research.

Figure. Development trends of the top five productive countries. TP: number of articles contain the keywords

Is Shared Decision-Making for Hemodialysis Adequate? The Rationale and Design of a Clinical Trial to Evaluate Video-Assisted Electronic Consent for Hemodialysis

Pedro H. Gois,[1,2] Rebecca Saunderson,[3] Marina Wainstein,[1,4] Kelly C. Li,[5] Matthew J. Damasiewicz,[6] Vera Y. Miao,[7] Kirsten S. Hepburn,[8] Martin Wolley,[8,1] Ann Bonner,[9] Helen G. Healy.[8,1] *[1]The University of Queensland Faculty of Medicine, Brisbane, QLD, Australia; [2]John Hunter Hospital, New Lambton Heights, NSW, Australia; [3]The University of Sydney Faculty of Medicine and Health, Sydney, NSW, Australia; [4]West Moreton Hospital and Health Service, Ipswich, QLD, Australia; [5]Saint George Hospital, Kogarah, NSW, Australia; [6]Monash Medical Centre Clayton, Clayton, VIC, Australia; [7]Hornsby and Ku-ring-gai Hospital, Hornsby, NSW, Australia; [8]Royal Brisbane and Women's Hospital, Herston, QLD, Australia; [9]Griffith University, Nathan, QLD, Australia.*

Background: Current methods of informed consent have repeatedly been demonstrated to be inconsistent and inadequate. We hypothesise that quality informed consent improves decision-making and is key to preparing patients for hemodialysis (HD). Study aims: To demonstrate that video-assisted electronic consent (eConsent) (intervention) compared to standard paper-based consent (control) improves patient experience, with better comprehension, reduced anxiety, increased satisfaction, less decisional regret, and improved adherence.

Methods: This is a multi-center, open label, randomized controlled trial (RCT). Participants: Incident and prevalent adult HD patients randomised 1:1 to either the intervention or the control groups. Intervention group: Participants will be coached to an online platform that delivers a simple-to-understand video animation followed by a knowledge questionnaire prior to signing an eConsent form to receive HD. The animation, co-designed with consumers, will consist of human figures role-playing a patient-doctor interaction. Control group: Participants will be consented by a clinician and sign a paper form. All groups will have any questions answered by a clinician prior to consent. Figure 1 depicts the RCT design and outcomes of interest.

Results: This RCT outcomes directly address patient experiences in the decision-making processes for HD. It will also standardize the content of complex HD health information, which may impact in decision-making and patient satisfaction.

Conclusions: If video-assisted eConsent is proven superior to the existing consent process, this RCT will serve as a proof-of-concept for changes in nephrology.

Funding: Government Support - Non-U.S.

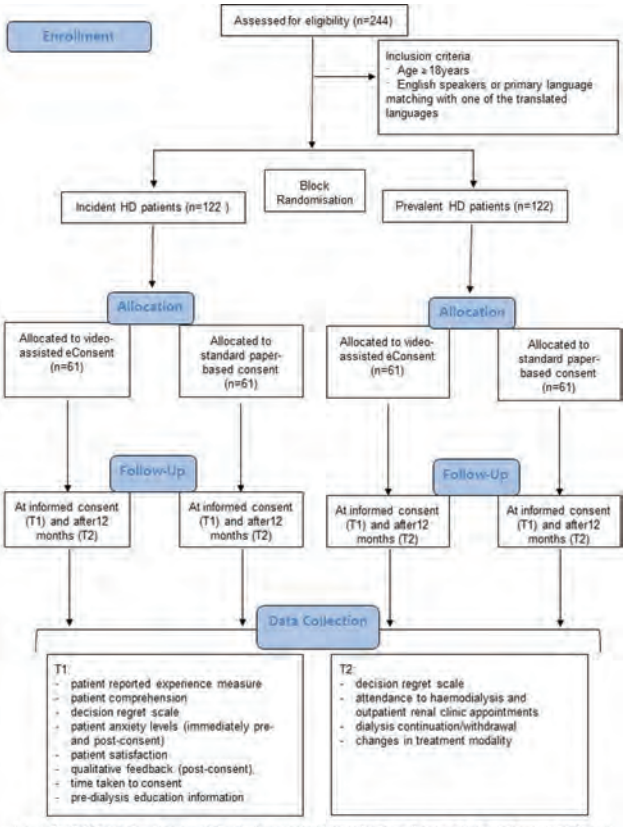

Figure 1: CONSORT flow diagram of the study protocol. Data collection will occur at informed consent (T1) and after 12 months (T2). Primary outcomes: Patient reported experience measure (modified Kidney PREM) and patient comprehension measured using an 18-point questionnaire previously published. Secondary outcomes: Validated decision regret scale, patient anxiety levels (six-item short form of the Spielberger State-Trait Anxiety Inventory), patient satisfaction (five-point Likert scale), compliance to renal care (attendance to HD and outpatient clinic appointments), dialysis continuation/withdrawal, changes in treatment modality, time taken to consent and participants' qualitative feedback.

PUB059

Impact of Behavioral Health on Kidney Disease Progression and Cost: Retrospective Analysis

Saravanan Balamuthusamy.[1,2] [1]*Texas Christian University Anne Burnett Marion School of Medicine, Fort Worth, TX;* [2]*PPG Heath, Fort Worth, TX.*

Background: Kidney disease can be impacted by other chronic conditions like cardiovascular disease and Diabetes. However, the impact of mental health on the progression of kidney disease and its impact on cost is unclear.

Methods: Retrospective analysis of 538,009 patients from a health analytics database was utilized for the analysis. Patients were stratified with and without behavioral health diagnosis. Patients with BHD were identified using relevant ICD-1, CPT codes and BH drug utilization for at least 3 months. Patients at risk for progression to high and ultra-high risk kidney disease were assessed using three different ML models (XG Boost, SVP and Random Forrest). Cost prediction across patients with and without behavioral health for risk or kidney disease progression was assessed from claims records.

Results: The mean age of the analyzed cohort is 55+/- 22, and 59% were males. The prevalence of kidney disease was 16.4% in patients with BHD. The risk of progression to high and ultrahigh risk kidney disease was 1.05 (1.03-1.06, $p < 0.001$) in patients with BH diagnosis. The average cost per member amongst patients with BHD at risk for progression to high-risk kidney disease is $54,989.97 vs $87,797.

Conclusions: There is a significant impact of BHD on kidney disease progression and its cost consequences. Risk stratification based on BHD is necessary while predicting disease to understand the true impact of disease progression so that appropriate case management and behavioral therapy strategies can be utilized to bend the cost and disease curve.

Image Segmentation Model Detects Abdominal Aortic Calcification in Dialysis Patients

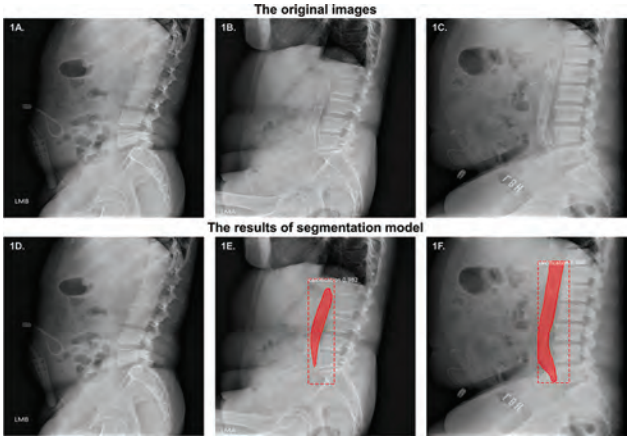
Chia-Tien Hsu,[1,2] Cheng-Hsu Chen,[1] Chin-yin Huang.[2] [1]*Taichung Veterans General Hospital, Taichung, Taiwan;* [2]*Tunghai University, Taichung, Taiwan.*

Background: Cardiovascular events remain the leading cause of death in patients with end-stage renal disease. Previous studies have established the considerable predictive value of the abdominal aortic calcification score in predicting cardiovascular morbidity and mortality. Our preliminary study aims to develop an artificial intelligence (AI) model using image segmentation to automatically detect abdominal aortic calcification.

Methods: This study analyzed 200 lateral view of abdominal X-ray images from patients who underwent dialysis. All included images were de-identified to protect patient privacy. We annotated the abdominal aortic calcification in the images using the "Labelme" marking tool and then split them into training and validation sets. For this image segmentation problem, we utilized the Mask-RCNN deep learning model. Furthermore, we randomly selected three extra abdominal X-ray images, separate from the initial dataset, for testing purposes. These three images consisted of one without calcification and two with calcification.

Results: After 30 training epochs, the loss was reduced to 0.1940, while the "val_loss" decreased to 0.2319. Subsequently, we tested our detection model on three extra images (Figure 1A~1C), and the results showed its ability to accurately predict the presence of abdominal aortic calcification. Figure 1D displayed the correct identification of an image without calcification, while Figure 1E and 1F demonstrated accurate detections of images with calcification. However, the model's boundary outlining didn't align precisely with the actual boundary. Improvement in this aspect of the model is needed.

Conclusions: AI has the potential to improve the accuracy and efficiency of healthcare delivery. The results of our preliminary study revealed that the AI assistant model successfully detected abdominal aortic calcification in the test images. Further investigation with a larger dataset and comparisons to other AI models are needed.



PUB061

Bone and Vascular Changes in CKD-MBD over 2 to 3 Years Analyzed by Artificial Intelligence

Hartmut H. Malluche,[1] Amr E. Mohamed,[1] Florence Lima,[1] Jin Chen,[1] Qi Qiao,[1] David Pienkowski.[2] [1]*University of Kentucky College of Medicine, Lexington, KY;* [2]*University of Kentucky, Lexington, KY.*

Background: Bone abnormalities and vascular calcifications occur with reduced GFR, but their relationships and progression are unclear.

Methods: Bone markers in serum and vascular calcifications were measured. Bone histology, Fourier transform infra-red spectroscopy of bone, and dual photon x-ray absorptiometry of hip and spine was done at baseline and after 2-3 years observation in 23 subjects with GFR 18-70 ml/min. Data were analyzed using artificial intelligence.

Results: Bone quality and quantity declined with early loss of GFR and were predicted by serum activin, FGF-23 and klotho. 18 subjects had baseline coronary or aortic calcifications: 52% and 65% rsp progressed. 5 subjects had no coronary calcifications at any time. Vascular calcifications were related to serum phosphorus levels. Increases in serum began at 4.0 mg/dl.

Conclusions: Serum markers offer promise as indicators of structural and cellular bone abnormalities accompanying early reduced kidney function. These include reduced bone quantity, quality and turnover abnormalities which are associated with coronary and aortic calcifications. Calcifications occur and progress in most studied subjects. Serum phosphorus levels ≥ 4.0 mg/dl predict vascular calcification progression.

PUB062

Prospective, Randomized Controlled Pilot Trial to Investigate the Impact of Artificial Intelligence (AI) on Shared Decision Making in Post-Kidney Transplant Care (PRIMA-AI): Study Protocol for a Randomized Controlled Trial

Bilgin Osmanodja, Klemens Budde. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Risk prediction models in kidney transplantation are ever increasing. Translation from good metrics to clinical benefit is the upcoming challenge. Another open question is how implementation of AI-based decision support systems (AI-DSS) affects physician-patient relationship in general and shared decision making (SDM) in particular.

Methods: In previous work, we developed risk prediction models for the prediction of infection, rejection and graft loss in kidney transplant recipients (KTR) and showed its superior performance in comparison to experienced physicians in a case-based reader study. Based on these models, we developed an AI-DSS that is implemented into the institutional electronic health record (EHR), and is studied in the PRIMA-AI trial.

Results: A 2-year, prospective, randomized, 2-armed, parallel group, single-center trial. KTR will be recruited in a German transplant center. All patients will receive the same routine care with clinical visits every 3 months. For patients in the interventional arm, physicians will be assisted by an AI-DSS that estimates 1-year risk for rejection, graft loss, or urinary tract infection (UTI). Based on the patients' risk scores, medical and SDM interventions will be suggested to the physicians per protocol. As primary endpoint, two scores for SDM, the CollaboRATE mean score, and the Control Preference Scale are compared between both groups at baseline and 12 months after randomization. Secondary endpoints address differences in patient and graft survival, rejection episodes, time from suspected rejection to biopsy, hospitalization for UTI, outpatient treatment of UTI, dialysis initiation via catheter or shunt, and patient-reported outcome measures. Qualitative semi-structured interviews with patients, support persons and physicians to study communication experiences and preferences as well as barriers and enablers of the implementation of AI-DSS in routine care and help interpret the quantitative data.

Conclusions: First, we investigate the potential benefit of an AI-DSS for the prediction of graft loss, rejection, and UTI in KTR. Additionally, using a mixed-methods approach, we aim to study the influence of AI-DSS on SDM, which can be relevant beyond the use case of kidney transplantation.

PUB063

A Systematic Review of Externally Validated Machine Learning Models for Predicting AKI in General Hospital Patients

Marina Wainstein,[1,2] Emily K. Flanagan,[1] David W. Johnson,[3,1] Sally Shrapnel.[1]
[1]The University of Queensland, Brisbane, QLD, Australia; [2]West Moreton Hospital and Health Service, Ipswich, QLD, Australia; [3]Princess Alexandra Hospital, Woolloongabba, QLD, Australia.

Background: Acute kidney injury (AKI) is one of the most common and consequential complications among hospitalized patients. Timely AKI risk prediction may allow simple interventions that can minimize or avoid the harm associated with its development. Given the multifactorial and complex etiology of AKI, machine learning (ML) models may be best placed to process the available health data to generate accurate and timely predictions.

Methods: We searched the literature for externally validated ML models developed from general hospital populations using the KDIGO AKI definition. Data extraction was done using the CHARMS and TRIPOD checklist and risk of bias was assessed using PROBAST.

Results: Of 889 studies screened, only four were retrieved that fit these criteria (Fig 1). While most models performed well and had a sound methodological approach, the main concerns relate to their development and validation in populations with limited diversity, comparable digital ecosystems, use of a vast number of predictor variables and over-reliance on an easily accessible biomarker of kidney injury.

Conclusions: These are potentially critical limitations to the applicability of ML models in diverse socioeconomic and cultural settings, prompting a need for simpler, more transportable prediction models which can offer a competitive advantage over the current tools used to predict and diagnose AKI.

Implementation of Risk-Stratified CKD Screening Among Patients with Type 2 Diabetes

Camilla Sammut-Powell,[1] Rose Sisk,[1] Susana Goncalves,[2] Shreyash Jain,[2] Luong Nguyen Cong,[2] Mark P. Edge,[1] Thomas D. Moitié,[1] Claudia S. Federico,[1] Ahmed Hadaoui,[2] Rory S. Cameron.[1] *[1]Gendius Limited, Alderley Edge, United Kingdom; [2]AstraZeneca PLC, Cambridge, United Kingdom.*

Background: A minimal-resource model to risk-stratify patients with type 2 diabetes for CKD screening has been developed and globally validated. However, it remains to understand how it can be best utilised in practice to support earlier identification of CKD. The CKD Screening Prioritizer (CSP) is risk-stratification tool powered by the minimal-resource model that can be integrated directly into existing systems or accessed via a user interface. This study aims to describe the implementation of the CSP within different technology systems with the goal of ensuring it is accessible to a broad spectrum of users.

Methods: Two core objectives of implementation were identified: 1. To determine the market need of the tool and 2. To determine the suitability and acceptance of implementation across several channels. Patients that were determined high risk by the CSP were recommended for serum creatinine testing. The total number of patients processed by the CSP and the proportion identified as high risk were measured across each implementation.

Results: The CSP was implemented across several countries via healthcare professional (HCP)-facing systems and direct to patients. HCPs were able to use the tool during face-to-face consultations on a per-patient basis or by processing entire clinic populations using historic patient records. Using a custom application-programming interface (API) we integrated with electronic health records. Chatbots within healthcare websites allowed direct-to-patient implementation: patients identified as high risk from this method were recommended to consult a healthcare professional on evaluating the next best course of action.

Conclusions: The CSP is a well-accepted and easily integrated risk-stratification tool that can be adopted across several settings. With the large and growing burden of type 2 diabetes, universal annual screening becomes an unrealistic target, particularly in lower resource healthcare systems. The CSP offers a novel solution to targeted CKD screening, enabling strategic allocation of healthcare resources, directing care to those who need it most and reducing system waste.

Construction of a Prediction Equation for the Progression and Worsening of CKD Using Artificial Intelligence

Koki Ogawa,[1] Yasushi Takahashi,[2] Seiko Oana,[2] Hiroaki Hara,[1] Tsukasa Odo,[2] Kento Soma,[2] Akito Maeshima,[1] Hajime Hasegawa.[1] *[1]Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]NEC Solution Innovators, Ltd., Koutouku, Japan.*

Background: Clinical studies in the past have focused on specific clinical characteristics (blood pressure, body mass index, renal function, urinary protein, various biochemical test parameters and specific markers, etc.) and analyzed their association with disease severity assessment, prognosis, and prediction of treatment responsiveness, mainly through statistical methods for specific populations. However, there are a wide variety of factors that can influence the above analysis, including age, gender, body size, presence and severity of comorbidities, and presence and type of medications, and so on. To conduct a more accurate and effective analysis, it is necessary to comprehensively consider the various data above for each individual. Against this backdrop, attempts to use various Ai(Artificial intelligence) algorithms to evaluate overall severity and predict future risk have been reported in certain fields in recent years. However, reports in the field of renal disease are limited. To develop a model to predict the risk of CKD progression and exacerbation using Ai, and to identify factors that have a significant impact on this exacerbation.

Methods: Data was collected from patients treated in our department from April 1 2006 to May 31 2021 with examination intervals of at least one year (3098 cases). The groups with the Green, Yellow and Orange stages of the CKD heatmap were analyzed at one year using Ai (rule discovery inference engine) to create a prediction equation. In addition to blood and biochemical test results, 209 factors were used in the analysis, including the name of the disease and drugs administered. A prediction equation was established using 85% of the cases in the population, and the accuracy of the prediction equation was verified by applying the obtained equation to the remaining 15% of cases. The final number of subjects for analysis was 1786 for Green, 824 for Yellow, and 488 for Orange.

Results: When the prediction formula was verified by the above method, the correct answer rate for each group was 76.8% for Green, 75.6% for Yellow, and 70.8% for Orange. Factors influential in CKD exacerbation at each stage were different.

Conclusions: The results of this analysis suggest that the relevant factors may have different priorities for each CKD stage.

PUB066

A New Deep-Learning Analysis Pipeline to Analyze and Quantify Renal Atrophy

Giuseppe L. Spatoliatore,[1] Alberto Rosati,[1] Guido Garosi,[2] Noemi La Francesca,[3] Clarissa Gambina,[4] Simone Cancelli,[4] Sergio A. Tripodi.[2] *[1]Ospedale di San Giovanni di Dio Firenze, Florence, Italy; [2]Azienda Ospedaliera Senese, Siena, Italy; [3]University of Siena, Department of Medical Biotechnology, Siena, Italy; [4]University of Siena, Department of Information Engineering and Mathematical Sciences, Siena, Italy.*

Background: atrophy represents a prognostic factor in many renal diseases and in kidney graft evaluation. Up to date the evaluation of atrophy is made using eyeball method and has low interobserver agreement. So, there is an urgent need to introduce user-friendly and affordable tools. Digital pathology coupled with AI represents the solution but is challenged by the need of long training of nets through large, annotated datasets. Annotations are manual, time-consuming and need skilled pathologists. Herein we propose a new method to annotate fast and well.

Methods: we have developed two new strategies to perform fast and accurate annotations. The first was the employment of immunostaining with CD10/PAS. CD10 brown decorates podocytes and the brush border of proximal tubules, Pas counterstain membranes pink. CD10 is under expressed in atrophic proximal tubules and absent in the distal nephron. Thus, it represents not only a morphological but also a functional marker. The second strategy was to speed up the annotation step using a new workflow (fig1).

Results: using our pipeline colours are well separated and the contours of the structures well delineated (fig2). Annotation time was dramatically shortened, and more than 10000 tubules were annotated in less than an hour compared with a mean of 24 hours of manual annotation and with a high variability depending on the skill of the operator.

Conclusions: we developed an easy fast method, based on AI, that combines morphology and immunophenotype. We wish to improve and standardize the morphofunctional evaluation of kidneys in nepropathology as well as in transplantation.

PUB067

Improving Outcomes of Patients with CKD by Employing Chronic Care Management Machine Learning Technology

Leigh J. Mack. *Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom.*

Introduction: Many patients today struggle with treatment plan adherence due to not understanding the plan or how prescriptions, diet, and exercise are all integral to improved outcomes. By employing personalized messages, two-way communications along with patient education, patients with chronic kidney disease take more interest and ownership in improving their condition. Patient follow-up after a clinical visit is key to improved outcomes. Many times patients do not fully understand the treatment plan and therefore do not follow it as prescribed. Initial contact is made by SMS text that is personalized to the patient from the physician. Patients were then asked to engage in a digitized questionnaire to measure prescription adherence, treatment plan compliance, and lifestyle choices along with specifics on diet and exercise.

Case Description: A total of 521 Medicare patients were enrolled in the service and followed up after 7 days after the last clinical appointment with the physician. Patients had a diagnosis of chronic kidney disease stage 3 through 5. Patients were contacted by SMS text and asked to call in to a service, employing the physician's digitized voice, asking the patient specific questions related to their condition. Patients were asked 20 questions every two weeks related to observable conditions, prescription adherence, treatment planned adherence, diet, exercise, overall health, and quality of care experience from the provider. Conversations were reviewed by a medical technician for the quality of responses and sentiment. The sentiment was measured using validated machine learning software. Cases were reviewed for 90 days, after which data was compiled with machine learning analytics software to analyze correlations. Specific data shall be presented as it relates to patient engagement and data analysis of all 20 questions.

Discussion: At the time of this submission data is still being gathered and expected to be completed by the beginning of September, 2023. Even though this was a large population, next steps might include lengthening the study to 6 months and enroll a population of over 10,000. A repository might be upwards of 50,000 and might include the patient's full EMR. As we explore more machine learning processes, we might expect the software systems to detect multifaceted clinical relationships.

PUB068

Application and Improvement of Interpretable Artificial Intelligence (AI) Algorithms Using Global Permutation Importance for Intradialytic Hypotension

Jian-An Wang,[1] Hsiang Wei Hu,[1] Kuanyu Chen,[2] Chi Hin Un.[1] *[1]National Cheng Kung University, Tainan, Taiwan; [2]AcuSense Biomedical Technology, Tainan, Taiwan.*

Background: In recent years, machine learning has made significant breakthroughs in the field of smart healthcare. Dialysis has also become part of smart healthcare. In Taiwan, it's 3,679 people per million undergoing dialysis, whereas the global average prevalence rate of intradialytic hypotension is 11.6% in the past study. Therefore, intradialytic hypotension makes the application of smart healthcare in blood dialysis an important topic. Several articles have used various machine learning algorithms to predict the occurrence of hypotension during dialysis. However, these prediction results often lack proper explanations or are too complex to understand. Therefore, this study aims to improve interpretable AI algorithms and proposes the Global Permutation Importance method as an example, which is the simplest and most interpretable algorithm.

Methods: The core of this method lies in "changing the object of explanation to achieve high interpretability." Due to the complex feature engineering and mathematical operations, some features in the dataset may have lost readability, and their explanatory results cannot be directly applied to the real world. Therefore, this study transfers the object of explanation to the raw data, namely the dataset without feature engineering. By randomly shuffling the features of this dataset and utilizing the established feature engineering and model, the impact of each feature on the prediction process is evaluated.

Results: The bar plots are used to interpret the results of feature importance. There are some features that are difficult to understand, such as time-related features and difference-related features. For example, the mean and median of the blood flow sequence cannot identify the differences in the world. It's difficult to interpret how these features impact the prediction. However, all of the features become useful and meaningful using global permutation importance, such as blood flow and body temperature. Additionally, feature engineering can evaluate whether the feature engineering has an effect on the prediction.

Conclusions: Through the aforementioned techniques, our explanatory results not only cover the model training and feature engineering processes but also enable healthcare professionals to fully understand the explanations, thereby increasing trust in the model and prediction results.

PUB069

In Vitro Iohexol Adsorption in Cartridges with Mesoporous Styrene-Divinylbenzene Sorbent

Thiago A. Reis,[1,2] Gonzalo Ramirez Guerrero,[3] Valentina Corradi,[3] Massimo de Cal,[3] Anna Lorenzin,[3] Claudio Ronco,[3] Monica Zanella.[3] *[1]D'Or Institute for Research and Education (IDOR). São Luiz Itaim Hospital, São Paulo, Brazil; [2]Laboratory of Molecular Pharmacology, University of Brasília, Brasília, Brazil; [3]International Renal Research Institute of Vicenza, Vicenza, Italy.*

Background: A strong rationale supports the removal of iodinated contrast media because of its nephrotoxicity. In this experiment, we aimed to investigate the efficacy of iohexol (molecular weight 821 Da) adsorption with a mesoporous styrene-divinylbenzene sorbent using an in vitro model.

Methods: We used a 0.9% NaCl solution spiked with iohexol in a closed-loop circuit. The circuit had a cartridge with adsorbing resin interposed downstream of a peristaltic pump. A glass reservoir in which the inlet and outlet lines were placed contained 1,000 mL of the saline solution with iohexol. The cartridge was filled with 75 g sorbent resin beads. The concentration of iohexol was assessed by high-performance liquid chromatography with ultraviolet (HPLC-UV) detection. The collection of 2 mL aliquots occurred at eight-time points (0, 5, 10, 15, 20, 30, 40, and 60 minutes).

Results: The reduction ratios after 5, 30, and 60 minutes were 24,5%, 47,5%, and 56,1%, respectively. In the second experiment, the reduction ratios after 5, 30, and 60 minutes were 22,5%, 44,1%, and 50,5%, respectively. After 30 minutes, the adsorption curved plateaued, indicating cartridge saturation.

Conclusions: Removing iohexol via adsorption was effective, with each gram of sorbent removing roughly 105 mg of iohexol (i.e., equilibrium load of 105 mg/g). The use of adsorption has the clinical potential to reduce exposure to nephrotoxic contrast agents.

Vancomycin Adsorption in Cartridges with Mesoporous Styrene-Divinylbenzene Sorbent Enhanced by Vibration

Gonzalo Ramirez Guerrero, Thiago A. Reis, Anna Lorenzin, Massimo de Cal, Claudio Ronco, Monica Zanella. *International Renal Research Institute, Vicenza, Italy*.

Background: Flow distribution inside the cartridge is one of the main issues concerning the performance of the sorbent. The packed beads can be approximated as a bundle of capillary tubes with some wide-diameter channels and gaps in the structure resulting in "channeling of the flow," avoiding complete contact with the beads. Fluid dynamics studies have shown different local velocities in the cartridge, determining the production of vortices; these may enhance contact time between blood and beads. Transverse vibration induces a substantial amount of radial mixing in the fluid. It creates a swirling or spiraling motion in the fluid, represented by vorticity contours with the potential beneficial effects of increasing contact time.

Methods: The circuit had a cartridge with adsorbing resin interposed downstream of a peristaltic pump. A reservoir in which the inlet and outlet lines were placed contained 1,000 mL of the saline solution with 10 g of vancomycin. The resin originated from HA380 cartridge. The GALILEO machine propelled the solution via a peristaltic pump for human hemoadsorption therapy. For each study point, a sample was drawn at 5, 10, 15, 20, 25, 30, 40, 60, 80, 100, and 120 minutes. Vibration was implemented with a speed at 1800 percussion per minute, amplitude of 10 mm, and frequency of 30 Hz. The device was installed in front of the cartridge, specifying the middle segment of the cartridge as the contact area. The reduction ratio was calculated using the formula: *[Initial concentration - Final concentration]/Initial concentration*

Results: Reduction ratios after 5, 10, 15, 20, 25, 30, 40, 60, 80, 100 and 120 minutes were 12,5%, 26.3%, 27.6%, 25.8%, 20.4%, 31.4%, 33.1%, 42.1%, 43%, 47.4% and 50%, respectively. A higher vancomycin reduction rate was observed in the first 20 minutes. Subsequently, the obtained curve was similar to a previous experiment without vibration after 20, 40, 60, 80, 100 and 120 minutes.

Conclusions: In this in vitro model, removing vancomycin via adsorption appears to be greater in the first 20 minutes when using vibration to accentuate this technique. Vibration in adsorption to increase performance warrants further investigation.

Ion Chromatography Study of Ca/Mg Phosphate Binders

Deanna J. Nelson.[1,2] *[1]BioLink Life Sciences Inc, Cary, NC; [2]NC State University, Raleigh, NC.*

Background: Ca and Mg are each well-known phosphate-binding cations. However, combinations of these cations provide unique clinical benefits in addition to phosphate (Pi) binding. Both in clinical studies and long-term use, increases in serum Mg were small and self-limiting, an unusual finding. To rationalize these reports, an *in vitro* Pi-binding study was completed using combinations of soluble Ca & Mg salts.

Methods: In a typical Pi-binding experiment, known quantities of Ca salt and Mg salt were incubated at 37 °C with a second, known quantity of Pi in buffer solution (0.1 N acetate, pH 4.5; or 0.1 N borate, pH 6.8). The solution pH was not adjusted after mixing. Aliquots were removed and filtered. Portions of the filtrate were diluted before analysis in triplicate for Ca and Mg using a validated ion chromatography method.

Results: Experimental data showed that combinations of Ca & Mg salts (110 mg Ca, 60 mg Mg) failed to bind Pi in acetate buffer, pH 4.5. (Ca acetate binds about 60% of available Pi under these conditions.) In contrast, in pH 6.8 borate buffer, rapid & extensive Pi binding was observed. Most of the Ca was bound to Pi & precipitated, but 65% of Mg remained in solution, even after extended lengths of time.

Conclusions: These observations strongly suggest combinations of soluble Ca and Mg salts react with Pi differently from Ca or Mg alone. At values of pH characteristic of the small intestine, the two cations rapidly precipitated Pi. However, over half of the Mg ion remained in solution under these conditions. The data suggest that residual Mg ion remains in solution after Pi-binding takes place in the upper intestine. If residual Mg is not absorbed, it acts beneficially in the colon. Conversely, if Mg is absorbed, it acts beneficially in the systemic circulation and intracellularly. Normalization of systemic Mg self-limits further absorption of the ion.

Prevalence and Factors Associated with Renal Hyperparathyroidism Among Dialysis-Requiring Patients

Bai Ramlyn G. Solaiman, Jennifer Ivy Togonon-Leaño, Jose Paolo P. Panuda. *Southern Philippines Medical Center, Davao City, Philippines*.

Background: Renal hyperparathyroidism, a CKD complication, is associated with increased parathyroid hormone levels from calcium, phosphate, and Vitamin D imbalances. It is 12-54% prevalent worldwide and associated with significant mortality and morbidity. This study aimed to determine the local prevalence and the factors associated with it among dialysis patients.

Methods: A cross-sectional study was conducted wherein all ESRD patients aged 19-75 years old and on maintenance dialysis ≥3months were included. The mean intact parathyroid hormone (iPTH), Vitamin D, ionized calcium, phosphorus and alkaline phosphatase were recorded. Correlation of age, gender, pre-dialysis co-morbidities, dialysis vintage and frequency were determined using spearman rank correlation coefficient, chi-square test and regression analysis.

Results: A total of 240 chronic dialysis patients in our unit were identified. Out of the 240 patients, 168 patients were included. There were 147 patients with elevated iPTH, giving an 87.5% prevalence. Age was negatively correlated with iPTH (r=-0.212, p=0.006, 95%CI-0.352,-0.062) and as they age, their iPTH is predicted to decrease by 15.195pg/mL (p=<0.01). Dialysis vintage had positive correlation with iPTH (r=0.369, p=<0.01, 95%CI0.227,0.512) and the longer they were on dialysis, their predicted iPTH will be higher by 93.637pg/mL (p=<0.01). Dialysis frequency was positively correlated with iPTH (r=0.19, p=0.016, 95%CI 0.036,0.344) and the more frequent their sessions were, their predicted iPTH will increase by 353.508 pg/mL (p=<0.012). Three pre-dialysis co-morbidities showed positive correlation with iPTH and their presence can

increase the iPTH significantly {hypertensive nephrosclerosis: x^2=9.44; p=0.024, diabetic kidney disease: x^2=19; p=<0.01, chronic glomerulonephritis: x^2=12.680; p=<0.01}.

Conclusions: The 87% prevalence rate supported the high prevalence world-wide. Factors identified were age, presence of pre-dialysis co-morbidities, longer dialysis vintage, and frequent dialysis sessions (3x a week). Shorter dialysis interval stimulates parathyroid gland from increased blood flow triggered during dialysis and altered calcium handling by the kidneys, subsequently leading to hormone secretion.

PUB073

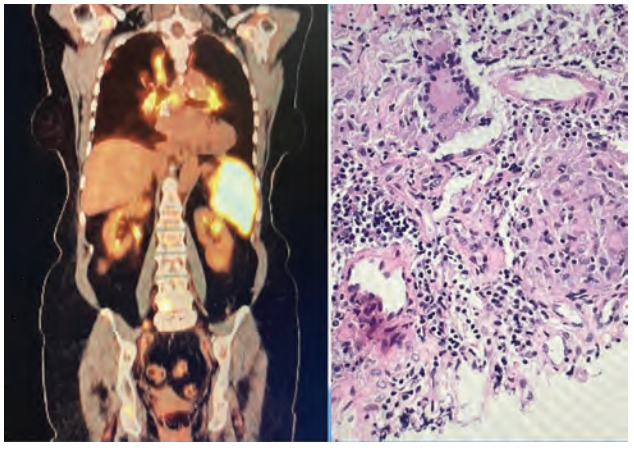
Hypercalcemia as a Solitary Feature of Sarcoidosis

Amandeep Singh,[1] Jon C. Webb,[1] Virgilius Cornea.[2] Pearl in the Oyster.
[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.

Introduction: In over 90% of cases, sarcoidosis typically manifests initially in the intra-thoracic region, characterized by mediastinal or hilar lymphadenopathy (LAD). It is rare for sarcoidosis to present solely as extra-thoracic, and even rarer for hypercalcemia to be the only initial sign.

Case Description: A 70-year-old Caucasian female with history of childhood histoplasmosis, presented with hypercalcemia of 12.2 mg/dl and elevated 1,25 dihydroxy vitamin D3 (1,25(OH)2 D) of 123 pg/ml. A chest CT revealed calcified lymph nodes (LN) in the mediastinum, indicating a previous histoplasmosis. PET-CT showed extensive generalized LAD with increased FDG uptake in the enlarged spleen. Additionally, myocardium showed no abnormal metabolic activity. An inguinal LN biopsy demonstrated non-necrotizing granulomatous inflammation. Staining with Grocott Methenamine Silver (GMS) and AFB was negative for organisms. Histopathology was negative for malignancy or lymphoma. Results of Fungitell, QuantiFERON TB gold, antibodies against Histoplasmosis, Blastomycosis, and Coccidiomycosis were all negative. Treatment with prednisone at 0.5 mg per kg led to the normalization of calcium and 1,25(OH)2 D levels within three weeks.

Discussion: The measurement of vitamin D metabolites is crucial for diagnosing hypercalcemia mediated by 1,25(OH)2 D. Granulomatous disease can lead to hypercalcemia and elevated 1,25(OH)2 D, therefore, should be considered in the differential diagnosis of hypercalcemia. When diagnosing sarcoidosis, other potential causes of granulomatous inflammation are typically ruled out by clinical features, laboratory findings, imaging, and tissue histopathology (as described under case description). A PET-CT scan is an essential tool in determining an appropriate biopsy site and excluding potential cardiac involvement of sarcoidosis.1,25(OH)2 D mediated hypercalcemia is responsive to glucocorticoid therapy.



High FDG uptake in spleen. H&E slide demonstrate non-necrotizing granuloma in the lymph node tissue.

PUB074

Giant Bladder Stone in a Young Male: When Surgery Complements Medicine for Better Outcomes

Gagan Aulakh,[1] Meghan E. Lacovara,[1] Arshdeep Singh,[2] Khushi Bhatia,[2] Yaseen Baseer.[1] *[1]Jersey City Medical Center, Jersey City, NJ; [2]Government Medical College Amritsar, Amritsar, India.*

Introduction: Bladder stones are extremely rare especially more than 100 grams. This is a case of giant bladder stone in 49 years old male with recurrent UTI and foreign body retention leading to open cystolithotomy.

Case Description: 49-year-old male with PMH of recurrent UTI and recurrent nephrolithiasis (lost follow-up with double J stents and nephrostomy tube) evaluated for symptomatic UTI. He denied family history of nephrolithiasis, Crohn's disease, or consumption of supplements. Blood workup revealed leucocytosis and hyperchloremic normal anion gap metabolic acidosis with normal potassium. Urinalysis showed turbidity with pH of 8.5, moderate triphosphate crystals, and positive for nitrite and LE. Radiology showed large urinary bladder calculus, bilateral hydroureteronephrosis with encrusted ureteral stents and staghorn calculus in left kidney. ESBL proteus mirabilis grew in blood and urine cultures. General urology and interventional radiology stepped out as extremely encrusted stents made high-risk with usual procedures. As an end resort surgical urology stepped in for multi-modal endourological approach starting with open cystolithotomy. Cystoscopy during surgery was performed which ruled out intravesical obstruction. Stone biochemical showed mixture of struvite and calcium apatite.

Discussion: Open cystolithotomy is preferred over transurethral cystolitholapaxy for large stones.

PUB075

Novel Markers of Early CKD-MBD Pathophysiology That Predict CKD Progression and All-Cause Mortality in Patients with Predialysis CKD

Shunsuke Yamada, Shigeru Tanaka, Shumei Matsueda, Takanari Kitazono, Toshiaki Nakano. *Kyushu University, Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Fukuoka, Japan.*

Background: CKD-MBD develops in the early stages of CKD and contributes to the increased risk of end-stage kidney disease and mortality. Thus, it is critical to identify new indicators that reflect early events of CKD-MBD and can predict mortality in the pre-dialysis stage of CKD.

Methods: We examined 4,308 patients enrolled in the FKR study, a prospective observational study of patients with pre-dialysis CKD stages G1–G5. We focused on fractional excretion of phosphate (FEP) and estimated phosphate concentration in proximal tubular fluid (ePTFp) as indicators of early CKD-MBD pathogenesis. We compared the onset of change in each indicator with the serum PTH, calcium, and phosphorus levels using baseline data. Additionally, we determined the association of FEP or ePTFp with the risk of all-cause mortality and composite renal event using longitudinal data. The composite renal event was defined as the development of end-stage renal failure and/or 1.5-fold increase in serum creatinine concentrations.

Results: Over 5 years, 1,488 patients developed a composite renal event and 423 died. FEP and ePTFp were elevated as early as an eGFR of 70 mL/min/1.73m^2 and preceded the changes in serum PTH, calcium, and phosphorus concentrations. Multivariate-adjusted Cox proportional hazard regression analyses revealed a significant association between FEP and ePTFp increase and a heightened risk of developing a composite renal event and all-cause mortality. The hazard ratio (95% confidence interval) for a 1 standard deviation increase in log FEP and log ePTFp was 1.36 (1.20–1.54) and 1.39 (1.21–1.59), respectively. This association was independent of the serum PTH, calcium, and phosphorus concentrations and remained almost unchanged on application of competing risk regression analysis.

Conclusions: FEP and ePTFp may serve as indicators of early CKD-MBD pathophysiology that predict CKD progression and all-cause mortality in patients with pre-dialysis CKD.

PUB076

Beyond Bones: Examining Vascular Calcification in Hemodialysis Patients and Its Association with Bone and Mineral Metabolism

Abdullah I. Hamad, Tarek A. Ghonimi, Tarek A. Fouda, Rania A. Ibrahim, Mincy Mathew, Heba M. Ateya, Sahar Aly, Yoldez Zitouni, Anees J. Alomari, Mohamad M. Alkadi, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: Patients on dialysis are at an increased risk of cardiovascular disease (CVD). The presence of vascular calcification (VC) is predictive of CVD and mortality. This study aimed to evaluate the possible relationship between VC and bone and mineral metabolism (BMD) in patients on dialysis.

Methods: This study was conducted in all ambulatory dialysis centers in Qatar from January to December 2022. We retrospectively reviewed dialysis patients' charts, including patient demographics, comorbidities, BMD parameters (corrected calcium, phosphorus, PTH, and Vitamin D3), and average medication doses per week. In addition, VC was assessed by echocardiography, abdominal and chest X-ray, and abdominal CT.

Results: 842 HD patients were included during the study period. VC was detected in 52.6% of patients (most commonly in the mitral valve with 55.5%). Patients with VC were older age (61.6±14.2 vs. 58.0±16.3 years, p 0.001), had diabetes mellitus (DM) (75% vs. 29%, p 0.006), Higher vitamin D levels (39.0±18.0 vs. 32.1±17.2 p=0.003), and higher 1α-hydroxyvitamin D3 and cinacalcet doses (p<0.001) compared to patients without VC. All other parameters were not different. Regression analysis (univariate and multivariate) for risk factors associated with VC is shown in Table 1. In multivariate analysis, age and diabetes were significantly associated with risk of VC (OR 1.049, p< 0.0001 and OR 1.768, P<0001) respectively). In addition, higher vitamin D levels and higher doses of 1α-hydroxyvitamin D3 were significant risk factors for calcifications (OR 1.017, p 0. 007 and OR 1.178, p <0.0001 respectively).

Conclusions: We found a high prevalence of vascular calcification among our hemodialysis cohort. Risk factors for VC were identified, including old age, DM, high vitamin D level, and high 1α-hydroxyvitamin D3 dose.

Funding: Government Support - Non-U.S.

Table 1: Regression analysis of risk factors for vascular calcifications in hemodialysis patients

	Univariate Analysis			Multivariate Analysis		
	OR	95%CI	P- Value	OR	95%CI	P- Value
Age	1.054	1.042-1.065	<0.001	1.049	1.033-1.065	<0.001
Diabetes	2.653	1.958-3.595	<0.001	1.768	1.128-2.772	0.013
Vitamin D Level	1.013	1.004-1.021	0.002	1.017	1.005-1.030	0.007

Symptomatic Hypercalcemia Secondary to Hyperthyroidism

Katrina Lamont, Roberto L. Collazo-Maldonado, Victor A. Canela-Samaniego. *Methodist Health System, Dallas, TX.*

Introduction: Hypercalcemia is often encountered in clinical medicine. The most common causes of hypercalcemia include primary hyperparathyroidism, iatrogenic causes (medications) and malignancy, while a rare cause is hyperthyroidism. This case highlights a nursing home resident presenting with severe hypercalcemia and undiagnosed thyroiditis.

Case Description: A 58-year-old AA woman with PMHX of CVA on PEG tube feedings presented with sudden onset non-exertional chest pain. The emergency department consulted the Nephrology service for evaluation of severe hypercalcemia and AKI. Medication list included aspirin, statin and citalopram. On exam, her PEG tube was in place, reflexes and vital signs were normal but was hypovolemic. Initial serum chemistries showed a BUN 67 mg/dl, serum Cr was 1.4 mg/dl, (SCr baseline <1 mg/dl). ALP 317 U/L, AST 283 and ALT 317 U/L respectively. CK was normal. Calcium was 13.4 mg/dl, albumin 3.5 g/dl. PTH was suppressed at 17 pg/ml, ionized calcium was 1.67 mmol/L. PTHrP was 5 pmol/L. Vitamin D 25-OH Vitamin D 1,25-OH were normal. SPEP and UPEP had no signs of monoclonality. TSH was extremely suppressed at <0.02 ulU/ml. T4 was high at 4.12 ng/dl and T3 was 5.13 pg/ml respectively. Thyrotropin receptor antibody was 3.23 IU/L and thyroid peroxidase antibodies titer was 278.2 IU/ml. U/A was normal. Urine drug screen was negative. Renal U/S had normal kidneys. A thyroid ultrasound showed a diffusely heterogenous in echogenicity with abnormal increased vascularity throughout. EKG had sinus tachycardia. The patient was treated with volume expansion with normal saline, pamidronate and calcitonin. Her serum calcium on discharge decreased to 10.7 mg/dl. She was treated with methimazole and propranolol for newly diagnosed Grave's thyroiditis. Her symptoms resolved and she returned to her nursing home.

Discussion: causes increased osteoclastic activity leading to bone resorption. Prompt recognition and early treatment of the hyperthyroid state is essential.

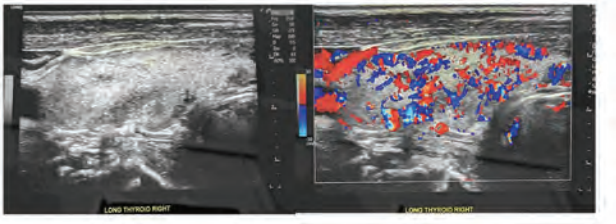

Figure 1. Transverse (a) sonographic and (b) Doppler ultrasound images of the thyroid gland showing diffuse echogenicity with increased vascularity, respectively.

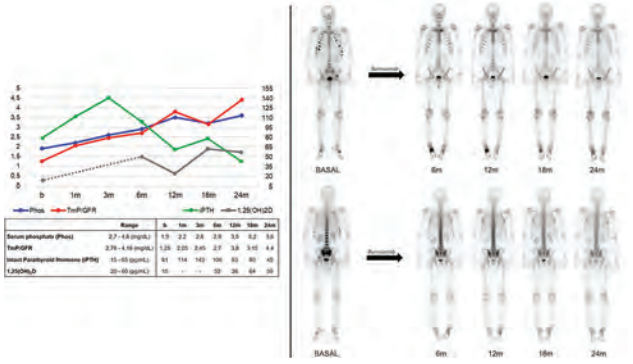
Burosumab Effects on Osteomalacia: A Tumor-Induced Osteomalacia (TIO) Case Report

Nadia Edvige Foligno,[1] Hajime Kato,[2] Yoshitomo Hoshino,[2] Soichiro Kimura,[2] Naoko Hidaka,[2] Takashi Sunouchi,[2] So Watanabe,[2] Teresa Arcidiacono,[1] Arianna Bologna,[1] Federica Giambò,[1] Giuseppe Vezzoli,[1] Nobuaki Ito.[2] *[1]Nephrology and Dialysis Unit, IRCCS San Raffaele Hospital, Milan, Italy; [2]Division of Nephrology and Endocrinology, The University of Tokyo Hospital, Tokyo, Japan.*

Introduction: Tumor-Induced Osteomalacia (TIO) is a rare paraneoplastic disorder caused by a tumor (PMT), usually of small size and benign, secreting FGF23. FGF23 suppresses the reabsorption of phosphate and the synthesis of 1,25$(OH)_2$vitD in the renal proximal tubule; consequently, affected patients develop hypophosphatemia and osteomalacia, resulting in bone pain and pathological fractures. The treatment of choice is the surgical resection of PMT, but when the latter is not detected or cannot be removed, phosphate salts and active vitD can be employed to improve symptoms. Burosumab, a monoclonal antibody directed against FGF23 introduced for XLH, has recently been tested for the treatment of TIO non-surgical patients, with encouraging results.

Case Description: Starting from January 2021, a 56M patient affected by TIO without identified PMT has been treated with burosumab 1mg/kg s.c./4w. Before the introduction of burosumab, his blood exams showed hypophosphatemia, low 1,25$(OH)_2$vitD levels and hyperparathyroidism secondary to previous administrations of phosphate salts. He also reported widespread bone pain, suspect of multiple fractures and pseudofractures, confirmed by whole skeleton bone scintigraphy (BS) as numerous areas of pathological accumulation in the ribs, sacrum, bilateral femur, right proximal tibia, sternoclavicular joint and vertebral bodies. After the initiation of burosumab, serum phosphate, PTH and 1,25$(OH)_2$vitD levels gradually normalized. The patient also reported an improvement in bone pain, and later BS described a notable and continuous reduction in pathological accumulations, which almost completely disappeared after 24m, confirming the absence of new fractures and the improvement of the existing ones.

Discussion: Therefore, burosumab is suggested as an alternative treatment for non-surgical TIO patients, especially since, unlike phosphate salts and active vitD, its therapeutic action seems to contribute to the further improvement of osteomalacia.



PUB079

Effect of Magnesium Supplementation on Serum Matrix Gamma-Carboxyglutamate Protein as Biomarkers of Vascular Calcification in Patients with CKD

Bancha Satirapoj, Pavitra Charoensrisakkul, Peeraya Permkarnjaroen, Narittaya Varothai, Narongrit Siriwattanasit, Naowanit Nata, Theerasak Tangwonglert, Amnart Chaiprasert, Ouppatham Supasyndh. *Phramongkutklao College of Medicine, Bangkok, Thailand*.

Background: Vascular calcification is a major risk factor of cardiovascular disease and cardiovascular mortality in patients with chronic kidney disease (CKD). Magnesium has pleiotropic potential for interfering with progression of vascular calcification by modulating the expression of anti-calcification proteins including matrix gamma-carboxyglutamate protein (MGP).

Methods: This study is double-blinded, randomized, placebo-controlled trial in CKD patients with high risk of vascular calcification. The subjects were randomly assigned (1:1) to receive oral magnesium dioxide (MgO2) 200 mg/day or matching placebo for 12 weeks. The primary end point was the between-groups difference in serum MGP level after 12 weeks.

Results: A total of 31 CKD patients (19 males and 12 females) were enrolled in the study. At baseline, mean serum magnesiumwas 2.05±0.23 mg/dL and baseline serum MGP levels did not differ significantly between the two groups. After 12 weeks, the mean MGP concentrations significantly increased in the MgO2 group (mean change, 90.45±102.06 ng/mL; 95%CI 209.45 to 219.80) and also significantly increased in the placebo group (mean change, 73.47±117.73 ng/mL; 95%CI 208.05 to 227.05). However, absolute MGP change was not significantly different between groups (P=0.682). There was no report of serious side effect or hypermagnesemia during the study.

Conclusions: Among CKD patients, magnesium supplementation for 12 weeks did not improve serum MGP level as biomarkers for preventing vascular calcification compared with placebo. Larger-scale trials are warranted to confirm these findings.

PUB080

Breaking Bad Calcium: The Role of Hemodialysis for Severe Hypercalcemia

Jeaneishka M. Rivera Rios, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera, Caleb S. Pacheco-Molina, Carlos G. Rivera-Bermudez. *Universidad de Puerto Rico Recinto de Ciencias Medicas, San Juan, Puerto Rico*.

Introduction: Hypercalcemic crisis is an emergent medical condition that may lead to serious complications such as acute kidney injury (AKI), muscle flaccidity, neurologic changes including obtundation and coma and cardiac arrhythmias leading to cardiac arrest. Standard treatment for hypercalcaemia includes saline hydration, bisphosphonates, steroids, calcitonin and in refractory cases, hemodialysis (HD). HD can effectively lower serum calcium levels but its use is not commonly reported by literature.

Case Description: A 48-year-old man with a right thigh mass as recently diagnosed with high grade sarcoma and bilateral pulmonary lesions was admitted for inpatient chemotherapy with cisplatin and doxorubicin was consulted to Nephrology service due to hypercalcemia. Patient was not taking any medications or had a prior history of renal disease. Vital signs with blood pressure 167/90 mmHg, heart rate 100 beats per minute, respiratory rate 20 breaths per minute, oxygen saturation 99% at room air and temperature 37°C. EKG showed QT shortening. Physical exam was remarkable for a critically ill patient oriented to person, dry mucous membranes, icteric sclera, large right thigh soft tissue mass with associated leg pitting edema +4 and palpable pulses. Laboratory results were significant for BUN 114 mg/dL, creatinine 3.69 mg/dL, bicarbonate 22.5 mmol/L, corrected calcium 19.4 mg/dL and intact PTH 40.86 pg/mL. Despite aggressive intravenous isotonic fluids, bisphosphonate and calcitonin administration, patient persisted with severe hypercalcemia. In view of altered mental status, EKG changes, worsening renal function and poor response to medical management, the patient was started on kidney replacement therapy with low calcium dialysate concentration. After 3 sessions of intermittent HD, serum calcium levels improved and treatment was discontinued.

Discussion: Hypercalcemia remains a medical emergency and the prompt diagnosis and management of underlying pathology are essential for adequate patient outcomes. Although not commonly used, HD is an efficient treatment for severe refractory hypercalcaemia as in our case or in whom aggressive fluid treatment is contraindicated. Along with conservative treatment, low calcium HD should be considered in patients with or without AKI, as severe hypercalcaemia is an indication for HD.

PUB081

Is There a Link Between Mineral Bone Disease, Ethnicity, and Kidney Transplantation?

Francisco Montero,[1] Thomas B. Coupe,[1] Rouven Calayag,[1] Rosa M. Montero.[1,2] *[1]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [2]King's College London, London, United Kingdom*.

Background: Health inequalities have been reported internationally to affect access to transplantation in ethnic minorities. It is unclear whether mineral bone disease treatments are also affected by this. Several studies have shown that there are ethnic differences in bone mineral metabolism that may further predispose kidney transplant recipients (KTR) to increased fracture risk, morbidity and mortality. Our centre serves a multi-ethnic population in South West London. This cross-sectional observational study looks at the current distribution of mineral bone disease medications and whether this is influenced by ethnicity.

Methods: All KTR active in the transplant programme in 2021-2022 were included. Data was collected from the electronic patient record. All those with a documented ethnicity were analysed together with biochemical markers and medications used for mineral bone disease. T-test and ANOVA statistical tests were used with significance $p<0.05$.

Results: 509 KTR with 40(8%) patients with unknown ethnicity were excluded. 469 KRT analysed: 45% White, 18% Black, 19% Asian, 2% Chinese, 8% other. 257 Male, 212 Female with a median age of 56yrs(21-87yrs). PTH levels were higher in Black people(18.8umol/L) and significantly decreased in all ethnicities($p<0.05$) between 2021-2022. Adjusted calcium levels were significantly increased in all ethnicities ($p<0.05$) except Chinese. Phosphate levels significantly decreased in all ethnicities($p<0.01$) and were higher in Asians. Creatinine was significantly raised in Whites compared to Asian and Other populations($p<0.05$) in 2021 but not seen in 2022. All ethnicities on Cinacalcet had significantly lower Creatinine in 2021($p<0.01$) and 2022($p<0.05$). All treatments were given to White persons with higher numbers on Cinacalcet+Alfacalcidol+VitaminD3 combination. Black persons were predominantly on Cinacalcet+Alfacalcidol, Asians on Alfacalcidol+VitaminD3 and Chinese on Cinacalcet. There was a significantly lower intake of Vitamin D3 in KTR($p<0.05$) in all ethnic groups.

Conclusions: There is a disparity in transplantation of ethnic minority groups with White persons predominantly being transplanted despite our multi-ethnic population. Treatment variations are seen between ethnic groups that can be multifactorial. These findings could suggest health inequalities and we are currently investigating potential drivers behind this.

PUB082

Bone Mineral Disorder in Patients with CKD Undergoing Hemodialysis Replacement Therapy at a Reference Center

Juan D. Diaz Garcia, Diana Maldonado Tapia, Enrique F. Morales Lopez, Francisco J. Hernandez Copca, Jose L. Ortega, Irving G. Ramirez, Julio C. Nieto, Beatriz R. Cerezo Samperio, Abel Humberto V. Compean, Mario Alamilla-Sanchez. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Background: Bone mineral disorder - conical renal disease is a syndrome that includes one or more alterations of: calcium, phosphorus, parathormone, vitamin D; remodeling, bone mineralization or volume, vascular or soft tissue calcifications. Generating high cardiovascular risk and fractures. Objective: To determine the prevalence of bone mineral disorder - chronic kidney disease in hemodialysis patients in a reference center.

Methods: Descriptive and association study, observational, cross-sectional, prolective, which included patients with chronic kidney disease on hemodialysis older than 18 years who agreed to participate. Sample size for prevalence of 60%, with alpha probability of 0.05 and precision factor of 0.1 was 93 patients, however, only 27 patients agreed to participate. Serum values of PTH, calcium, phosphorus, calcidiol, time on hemodialysis, age, sex, and presence of diabetes were obtained. Data processing analyzed with SPSS 22, ORP calculation with 95% CI, Chi square and logistic regression $p<0.05$.

Results: 90% prevalence of bone mineral disorder, prevalence of high turnover bone disease 81.2%. The association of vascular calcifications with age OR 1.324 IC (1.003 to 1.7) p 0.04, with PTH OR 1.001 IC (0.9 to 1.04) p 0.3 and with time on hemodialysis 3.4 (0.2-46.4) p 0.04.

Conclusions: In our population, the prevalence of bone mineral disorder is consistent with that reported in the literature. Our patients present a high frequency of vascular calcifications and a predominance of high turnover bone disease. The underdiagnosis of this disorder generates complications that have an impact on cardiovascular morbidity and mortality.

PUB083

Investigating Mesenchymal Stem Cell Sources for VEGFA mRNA Transfection and In Vivo Protein Exposure

Robert I. Menzies,[1] Cecilia Graneli,[1] Alex X. Zhou,[1] Xuechong Hong,[1] Ulrika Dahlqvist,[1] Vijayaganapathy Vaithilingam,[1] Mikko Hölttä,[1] Neil Henderson,[1] Stephanie M. Bates,[3] Mick D. Fellows,[3] Anna Forslöw,[1] Xiang yang Zhu,[2] Christine Ahlström,[1] Alessandro Boianelli,[1] Ryan Hicks,[1] Lilach O. Lerman,[2] Pernille B. Laerkegaard Hansen.[1] *[1]AstraZeneca, Gothenburg, Sweden; [2]Mayo Clinic Research Rochester, Rochester, MN; [3]AstraZeneca R&D Cambridge, Cambridge, United Kingdom.*

Background: Cell based therapies offer promising avenues for the treatment of kidney diseases. Among these, mesenchymal stem cells (MSCs) have shown potential due to their immunomodulatory properties. Recent advances in RNA-based technologies have opened up new avenues to enhance MSC functionality. Here we investigate the function of MSCs transfected with RNA encoding vascular endothelial growth factor-a (VEGFA), an important angiogenic protein in the kidney and other organs that is diminished in ischemic diseases.

Methods: Pig (adipose) and human (bone marrow, umbilical, adipose, or induced pluripotent) MSC sources were investigated for reproducible production of VEGFA protein following RNA transfection. VEGFA protein production from MSCs was then investigated *in vivo* in a mouse pharmacokinetic model and a pig model of renal artery stenosis.

Results: Reproducible and similar post-transfection expression patterns of VEGFA (6-8x10^6 pg/mL) were achieved in human bone marrow MSCs and porcine adipose tissue derived MSCs *in vitro*, with the prior demonstrating greater expansion potential. Healthy mice injected with VEGFA-MSCs showed transiently increased VEGFA protein levels in kidney. In renal artery stenosis pigs, injection of porcine VEGFA-MSCs produced a peak of VEGFA (3.95 pg/mg renal tissue; 6hrs post injection) which resolved by 10 hours. RNA transfection did not change the immunomodulatory capacity of MSCs nor their capacity for trilineage differentiation.

Conclusions: These data confirm a transient burst in VEGFA protein is achievable through RNA transfection of MSCs, delivered in a relevant disease setting. The pharmacokinetic parameterisation of MSC-based VEGFA protein production *in vivo* will inform future cell therapy development.

Hypoxic Preconditioning Alters Micro-RNAs Expression in Mesenchymal Stem Cells from Patients with Hypertensive Kidney Disease

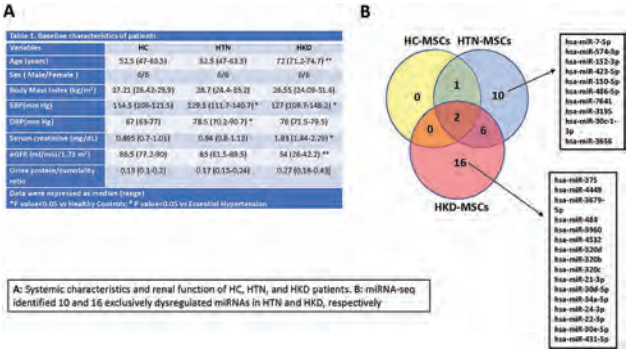
Gurparneet K. Sohi, Sara Kazeminia, Arjunmohan Mohan, Naba Farooqui, Alfonso Eirin, Lilach O. Lerman, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Hypertensive kidney disease (HKD) is a common cause of end-stage kidney disease. Autologous mesenchymal stem cells (MSCs) emerge as a therapeutic option for many kidney diseases, but HKD might alter their regenerative ability. Hypoxic preconditioning (HPC) enhances MSC functionality by modulating global gene expression. We hypothesize that HPC can promote MSCs function by altering their miRNAs expression.

Methods: MSCs were collected from abdominal subcutaneous fat biopsies of healthy controls (HC), hypertensive (HTN), and HKD patients (n=12 each, **Fig. 1A**). miRNA sequencing (seq) was performed on MSC cultured in normoxic (20% O_2) or hypoxic (1% O_2) conditions for 24-72h. Differentially expressed (DE) miRNAs (log fold>1.5 or <1.5; p<0.05) were identified followed by target predictions and gene ontology analysis.

Results: miRNA-seq identified 10 and 16 miRNAs altered by HPC exclusively in HTN and HKD, respectively (**Fig. 1B**). In HPC MSCs, the upregulated HTN miRNAs target genes were involved in telomere maintenance, DNA damage, and FGFR signaling, whereas downregulated ones were implicated in blood vessel development and growth regulation. Contrarily, upregulated HKD miRNAs target genes participate in TNF-α signaling and response to hormones, whereas downregulated ones were involved in VEGFA-VEGFR2 pathways and regulation of embryonic development.

Conclusions: HPC differentially influences the expression of miRNAs implicated in vascular development and cell senescence in human HKD- and HTN-MSCs and may thereby enhance angiogenesis and MSC regenerative capacity and blunt inflammation. Further studies are needed to explore the unique role of HPC in miRNAs expression and MSCs functionality in HKD.



A: Systemic characteristics and renal function of HC, HTN, and HKD patients. B: miRNA-seq identified 10 and 16 exclusively dysregulated miRNAs in HTN and HKD, respectively

PUB085

Osteopontin-Associated Reparative Effects of Selected Renal Cells

Andrew T. Bruce, Prakash Narayan, Tim A. Bertram, Deepak Jain. *ProKidney, Winston Salem, NC.*

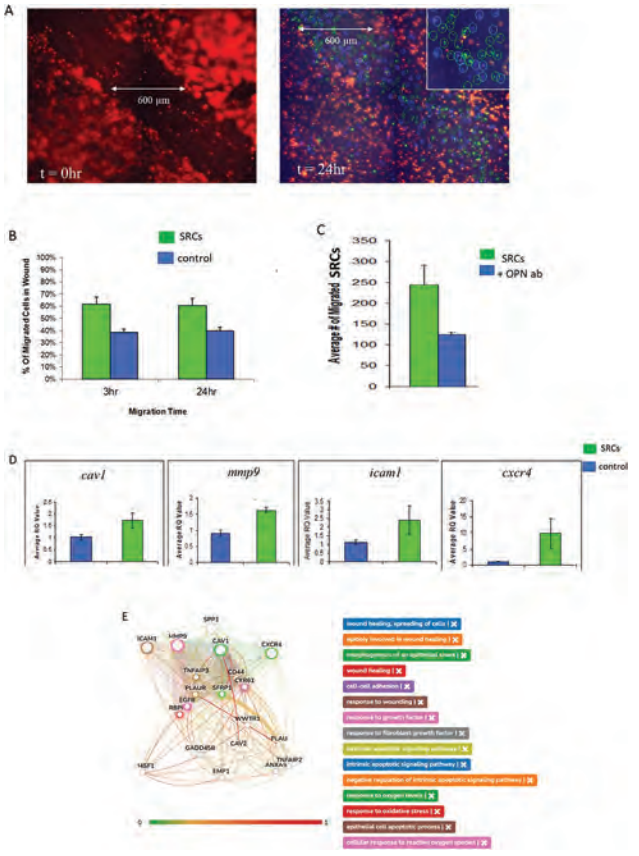
Background: Osteopontin (OPN) conveys renal reparative effects. Selected renal cells (SRCs), a glomerular- and tubular epithelial cell-enriched platform, exhibit reparative and restorative effects in models of CKD. In the present study, we tested the hypothesis that OPN mediates SRC reparative activity.

Methods: Human SRC (National Disease Research Interchange) and renal cortical biopsy (control) monolayers were submitted to a scratch assay in the absence/presence of an OPN neutralizing antibody (ab). Reparative activity was evaluated by imaging (blinded) the number of cells migrating to bridge the wound. Expression of *cav1*, *mmp9*, *icam1* and *cxcr4* was evaluated using qPCR. Genes were seeded into HumanBase for visualization of transcriptome function.

Results: Compared to control, SRCs exhibited increased migration into the wound (p<0.05), an effect reduced by the OPN ab (p<0.05). Expression of migratory markers *cav1*, *mmp9*, *icam1* and *cxcr4* was upregulated in SRCs (p<0.05). Gene ontology confirms that the *opn*/ssp1-*cav1*-*mmp9*-*icam1*-*cxcr4* axis regulates migration, adhesion, and wound healing in the kidney.

Conclusions: These data suggest that SRC associated preservation of renal microarchitecture and maintenance of the renal filtration function, including creatinine clearance, electrolyte balance, fluid homeostasis, urine concentration and Cystatin C metabolism, may be mediated, in part, by an OPN-associated wound healing cascade.

Funding: Commercial Support - ProKidney LLC.



(A) Renal wound healing assay. (B, C) SRCs exhibit increased migration into the wound, an effect reduced with OPN ab pretreatment. (D) SRCs exhibit upregulation of migratory genes *cav1, mmp9, icam1* and *cxcr4*. (E) The *opn*/ssp1-*cav1-mmp9-icam1-cxcr4* axis regulates renal migration, cell-cell adhesion, and wound healing.

PUB086

Selected Renal Cells Express Cell Adhesion Markers and Form Renal Tubules

Prakash Narayan, Andrew T. Bruce, Tim A. Bertram, Deepak Jain.
ProKidney, Winston-Salem, NC.

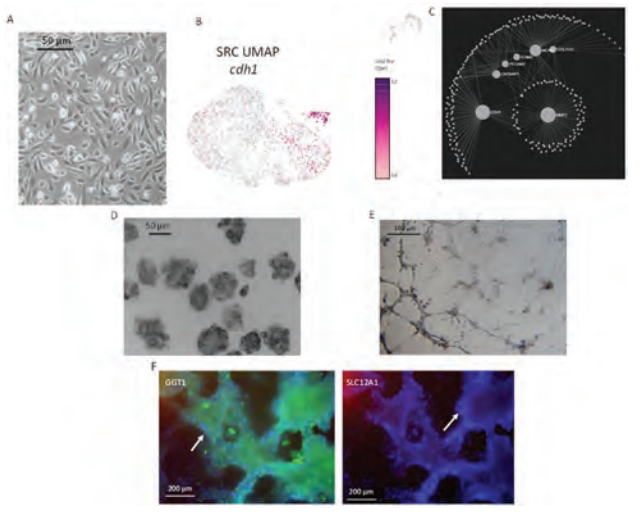
Background: Selected renal cells (SRCs) express podocyte, ureteric bud and cap mesenchyme markers and demonstrate renal reparative and restorative activity potentially by recapitulating events associated with embryologic kidney development. We tested the hypothesis that SRCs express cell-cell adhesion markers and form renal tubules.

Methods: Human SRCs (National Disease Research Interchange) were submitted to mRNA-seq for identification of differentially expressed genes (DEGs vs. source biopsy; P_{adj} <0.05), to scRNA-seq to map gene expression, and to flow cytometry for phenotypic marker identification. SRC cell-cell adhesion markers were identified using KEGG pathway analysis and their network visualized using miRNet.ca. SRCs were placed in culture±hydrogel for evaluation of renal tubule formation with antibody staining for epithelial markers GGT1 and SCL12A1.

Results: SRCs (A) exhibited upregulation (Log2FC) of cell-cell adhesion genes *icam5* (2.5), *mcam* (1.5), *cntnap1* (1.65), *col11a1* (3.1) and *mmp2* (2.1) and expression of PECAM1 and CDH1 (B). Gene ontology confirmed an interactome comprising these cell-cell adhesion markers (C). Placed in culture, SRCs assembled into organoids (D) which in the presence of hydrogel united to form renal tubules (E) expressing GGT1 and SCL12A1 (F).

Conclusions: These data suggest that the potential therapeutic activity of SRCs may be mediated in part via formation of renal tubules and therefore, maintenance of electrolyte balance, fluid homeostasis, reabsorption of essential nutrients, urine concentration and Cystatin C metabolism.

Funding: Commercial Support - ProKidney



SRCs (A) express cell-cell adhesion markers including CDH1 (B) that form an interactome (C). Placed in culture, SRCs form organoids (D) which, in the presence of hydrogel integrate into renal tubules (E) expressing GGT1 and SCL12A1 (F, arrows).

PUB087

Chronic Exposure of Melamine Accelerates the Progression of Kidney Injury in High-Fat Diet-Induced Obese C57BL/6 Mice and db/db Diabetic Mice

Miao-Yi Wu,[1] I-Hsuan Tsai,[1] Yi-chun Tsai,[1,2] Chia-Chu Liu,[1,2] Ming-Tsang Wu,[1,2] Tusty-Jiuan Hsieh.[1,2] *[1]Kaohsiung Medical University College of Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Research Center for Environmental Medicine, Kaohsiung, Taiwan.*

Background: Diabetes mellitus (DM) is the major cause of chronic kidney disease (CKD). Our previous studies have found that environmental melamine exposure is significantly associated with kidney function deterioration in patients with early-stage CKD. However, the underlining molecular mechanism is unclear yet. Whether melamine could promote the progression of CKD in DM remains to be clarified. In this study, we aimed to investigate whether chronic exposure of melamine could promote progression of kidney injury in DM.

Methods: We conducted two type 2 diabetic animal models, high-fat diet (HFD) induced model in C57BL/6 mice and db/db diabetic mice, with exposure of melamine at the mimic human tolerable daily intake (TDI) levels (2.5, 6.3 and 50 mg/kg body weight/day). Urine albumin-creatinine ratio (uACR) was used to monitor kidney function. We applied Periodic Acid-Schiff (PAS) staining, Masson trichrome staining, TUNEL assay and Western blotting to observe kidney injury, fibrosis, apoptosis and related protein expression.

Results: We observed an increased trend of urinary albumin levels in chow-diet (CD) and HFD with melamine exposure, indicating an early sign of kidney injury in the mice with hyperglycemia after 22-week exposure to melamine at the mimic human TDI levels. Even though serum BUN and creatinine levels remained normal, changes in kidney morphology were seen. According to the result of PAS staining, many renal tubular cells were damaged and formed vacuolation morphology. Tubulointerstitial fibrosis and apoptotic cells were more frequently to be seen the HFD mice coexposed with melamine. The protein biomarkers of inflammation (CD68, NF-kB phosphorylation), apoptosis (cleaved caspase 3) and fibrosis (active form of TGFb) were also increased. In db/db diabetic mice, we observed that serum creatinine and urinary total protein were significantly increased in the melamine exposure group. Tubulointerstitial fibrosis and urinary NAG (N-acetyl-β-D-glucosaminidase) level were significantly increased in the db/db mice exposed to melamine for 10 weeks.

Conclusions: Taken together, these results suggest that chronic melamine exposure may increase risk to accelerate the development of diabetic nephropathy.

Transmembrane Protein 72, Expressed in the Distal Convoluted Tubule, May Play a Potential Role in Diabetic Kidney Disease

Jianteng Xie, Qiuling Li, Wenjian Wang. *Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: Transmembrane protein 72 (TMEM72) is highly expressed in tubules of the kidney. This study is designed to explore the role and the potential mechanism of TMEM72 in the development of diabetic tubulopathy.

Methods: Serum TMEM72 concentration was tested in health control, patients with diabetes mellitus (DM) and diabetic kidney disease (DKD). The variation trend of TMEM72 was determined by immunohistochemistry on kidney tissues from patients in different stage of DKD. Immunofluorescence staining was performed with TMEM72, SGLT2, NKCC2 and AQP2 to identify the expression site of TMEM72 in mice renal

tubules. To investigate the potential cellular pathway that TMEM72 was involved, an immunofluorescence test was performed with TMEM72, LAMP1, Mito-tracker and Calnexin in cultured distal convoluted tubule (DCT) epithelial cells. Western blot was used to detect the activity of TMEM72 in HK2 cells following HG treatment.

Results: The concentration of serum TMEM72 was lower down in DM and DKD group when compared to the health control (P<0.001). The expression of TMEM72 also decreased gradually in human kidney tissue of different stage of DKD following the progression of disease. Co-localization of TMEM72 and NKCC2 in immunofluorescence staining indicated that TMEM72 was mainly expressed in DCT. Stimulated by different glucose concentrations, cell culture study (mouse DCT cell; human kidney-2 cell, HK-2 cell) in vitro showed that TMEM72 was down-regulated as the glucose concentration gradient rised. In immunofluorescence, the co-localization of TMEM72 and LAMP1 suggested that TMEM72 might be involved in lysosomal metabolic pathways and participate in the progression of DKD.

Conclusions: Our current study has revealed that TMEM72 may act as a novel participator in DKD by being involved in the renal tubular injury.

Anti-Fibrotic Gene Protects Kidney and Muscle Through Myokine-Mediated Organ Cross-Talk in Diabetic Kidney Disease Mice

Sehyun Jung,[1] Seunghye Lee,[1] Hyejin Jeon,[1] Hani Jang,[1,2] Jin Hyun Kim,[1] Se-Ho Chang,[1,2] Hyun-Jung Kim.[1,2] *[1]Gyeongsang National University Hospital, Jinju-si, Gyeongsangnam-do, Republic of Korea; [2]Gyeongsan National University College of Medicine and Institute of Health Sciences, Jinju-si, Gyeongsangnam-do, Republic of Korea.*

Background: The muscle-kidney crosstalk is emerging as a treatment strategy for kidney disease. Irisin is a beneficial myokine that improves kidney function and inhibits renal fibrosis via TGF-b1. This study investigated whether the anti-fibrosis gene (anti-F) as a negative regulator of TGF-b1, could demonstrate renoprotective effects through myokine modulation in db/db mice.

Methods: The db/db mice (5 weeks, male) were employed for a type 2 diabetic kidney damage. Mice were injected intraperitoneally with 40 μg of anti-F plasmid with TGF-ß promoter once a week for 16 weeks from 9 weeks, euthanized, and serum, muscles, and kidneys from all mice were harvested for analysis.

Results: The db/db mice showed worse kidney function parameters than db/m+ mice (Fig 1). In db/db mice, mRNA expression of irisin was downregulated in the muscle and kidney tissue. However, anti-F administration counteracted downregulation of irisin mRNA. Anti-F is involved in the reduction of muscle atrophy reflected by mRNA level for MuRF1 and in rising of muscle regeneration reflected by mRNA level for Myf1 in diabetic circumstances (Fig 2).

Conclusions: This study provides that anti-F could be a candidate that links "muscle-kidney crosstalk" related to the recovery of kidney damage from diabetes, and anti-F gene therapy might be one of options for treating patients with diabetic kidney disease.

Finerenone in Chinese Patients with Type 2 Diabetes and CKD: A FIDELITY Analysis

Ping Li,[1] Yu An,[2] Hongguang Zheng,[3] Weiping Lu,[4] Zhaohui Mo,[5] Xudong Xu,[6] Yibing Lu,[7] Chaoqing Wu,[8] Jingyuan Xie,[9] Nanwei Tong,[10] Fang Liu,[11] Qinkai Chen,[12] Yang Hu,[13] Meike Daniela Brinker,[14] Luke Roberts,[15] Dalong Zhu,[16] Zhihong Liu.[2] *[1]Nanjing University Medical School, Nanjing, China; [2]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [3]General Hospital of Northern Theatre Command, Shenyang, China; [4]The Affiliated Huaian No.1 People's Hospital of Nanjing Medical University, Nanjing, China; [5]The Third Xiangya Hospital of Central South University, Changsha, China; [6]Fudan University Minhang Hospital, Shanghai, China; [7]The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China; [8]The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, China; [9]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [10]West China Hospital, Sichuan University, Chengdu, China; [11]West China Hospital of Sichuan University, Chengdu, China; [12]The First Affiliated Hospital of Nanchang University, Nanchang, China; [13]Bayer Healthcare Company, Beijing, China; [14]Bayer AG, Cardiology and Nephrology Clinical Development, Wuppertal, Germany; [15]Cardiology and Nephrology Clinical Development, Bayer AG, Reading, United Kingdom; [16]Nanjing University Medical School Affiliated Nanjing Drum Tower Hospital, Nanjing, China.*

Background: Finerenone significantly reduced the risk of cardiorenal outcomes in patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) in the FIDELITY prespecified pooled analysis of the phase III FIDELIO-DKD and FIGARO-DKD trials. This FIDELITY subanalysis explored the efficacy and safety of finerenone in Chinese patients.

Methods: Of 13,026 patients, 697 from sites in China were self-identified as Chinese and were randomized 1:1 to finerenone or placebo. Eligible patients had T2D and CKD (urine albumin-to-creatinine ratio [UACR] ≥30–<300 mg/g and estimated glomerular filtration rate [eGFR] 25–≤90 mL/min/1.73 m^2, or UACR ≥300–≤5000 mg/g and eGFR ≥25 mL/min/1.73 m^2), and were on optimized renin-angiotensin system inhibition. Key outcomes were a kidney composite (kidney failure, sustained ≥57% eGFR decrease from baseline over ≥4 weeks, or renal death) and a cardiovascular (CV) composite (CV death, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure). A secondary kidney composite was kidney failure, sustained ≥40% eGFR decrease from baseline over ≥4 weeks, or renal death. Safety outcomes were assessed by treatment-emergent adverse events and laboratory evaluations (e.g. serum potassium).

Results: Finerenone reduced the risk of the primary and secondary kidney composite in the Chinese subgroup (hazard ratio [HR] 0.57; 95% confidence interval [CI] 0.38–0.86; p=0.0066 and HR=0.54; 95% CI 0.40–0.74; p<0.0001, respectively) vs placebo, with consistent effects on components such as kidney failure (HR=0.53; 95% CI 0.33–0.86; p=0.0094). The HR of the CV composite was 0.82 (95% CI 0.52–1.29) for finerenone vs placebo, consistent with that in the overall FIDELITY population. Overall safety outcomes were similar between treatment arms. Hyperkalemia leading to treatment discontinuation was low for finerenone (2.6%) and placebo (0.9%); the difference in mean serum potassium increase from baseline between finerenone and placebo was ~0.13 mmol/L from month 1 to 20.

Conclusions: Finerenone had cardiorenal benefits and a favorable safety profile in the FIDELITY Chinese subgroup.

PUB091

Association Between Neutrophil-Lymphocyte Ratio (NLR) and Clinical Outcomes Among Filipino Patients with ESRD Secondary to Diabetic Nephropathy on Maintenance Hemodialysis

Lovenia Anne C. Olores, Grecia Darunday, Eratosthenes S. Polito, Ruben A. Maguad. *Perpetual Succour Hospital, Cebu City, Philippines.*

Background: Evidence on the usefulness of neutrophil-to-lymphocyte ratio (NLR) as a prognostic biomarker in diabetes patients with chronic kidney disease is still scarce to date. This study aimed to determine the association between NLR and morbidity among Filipino patients with end-stage renal disease (ESRD) secondary to diabetic nephropathy on maintenance hemodialysis.

Methods: This was an observational descriptive, prospective cohort study that evaluated outpatient Filipino citizens aged >18 years diagnosed with ESRD secondary to type 2 diabetes mellitus (T2DM). All patients had good compliance to their hemodialysis regimen (i.e., at least twice weekly dialysis within the past 3 months). The patients were divided into two groups according to the baseline NLR value at a cut-off of 3.5 as the high NLR group (NLR ≥3.5) and the low NLR group (<3.5). The cutoff was based on data that a high NLR of ≥3.5 was correlated with increased inflammatory states leading to higher morbidity. Patients were followed up after 6 months, and data on the primary outcome measure of disease occurrence were collected.

Results: Of the 63 patients evaluated, majority (n=39, 61.9%) had a baseline NLR value of <3.5. The high NLR group included 24 (38.1%) patients; among them, 9 developed disease. In the low NLR group (n=39), only 2 patients developed disease. NLR was significantly correlated with clinical disease outcomes (p=<0.05).

Conclusions: A baseline NLR of ≥3.5 was associated with disease occurrence. In conclusion, patients with a high baseline NLR have increased inflammatory state and a higher risk of developing disease conditions than patients with an NLR <3.5. Thus, the baseline NLR value can be used to predict prognosis in T2DM patients with ESRD.

PUB092

Dapagliflozin in CKD Patients with Diabetes from a Real-World Study

Xiaocen Fu, Hong Ren, Jingyuan Xie, Yan Ouyang, Xiao Li, Nan Chen. *Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China.*

Background: Diabetes is one of main causes of chronic kidney disease (CKD), and it increases the risk of adverse outcomes including cardiovascular events, end stage renal disease and mortality. Dapagliflozin (DAPA), as a selective sodium glucose cotransporter 2 inhibitor, has been reported to be beneficial for CKD patients with diabetes in previous clinical trials, however, real-word evidence is limited, especially among Chinese population.

Methods: A total of 803 CKD patients with type 2 diabetes were included in China from January 2011 to December 2021. Eligible participants were adults with estimated glomerular filtration rate (eGFR) ≥20 ml/min/1.73m^2 and 24-hour urinary protein (24h-UP) of 300 to 3500 mg/24h. Both groups received a stable dose of RASi without immunosuppression therapy or >10 mg prednisolone daily. DAPA group received 10 mg DAPA once daily. Propensity score matching was applied to balance the baseline characteristics, including age, sex, eGFR, 24-UP, and hypertension history. The primary outcome was the change in 24h-UP from baseline at 6 months. Nonparametric tests were used to compare differences between groups.

Results: Of the 803 patients, 276 were in the DAPA group (mean age 55.6 yrs, male 66.3%, median eGFR 69.2ml/min/1.73m^2, median 24h-UP 1214.0mg/24h) and 527 in the control group (mean age 57.4 yrs, male 64.9%, median eGFR 72.1 ml/min/1.73m^2, median 24h-UP 858.0 mg/24h). After 6 months, DAPA significantly reduced 24-UP compared to the control group (-23.0% vs -4.51%, P<0.05). The reduction in uric acid was significantly greater in the DAPA group than in the control group at 6 months (-6.78% vs 0.51%, P<0.001). eGFR decreased significantly in the DAPA group compared to the control group at 3 months (-2.50% vs -0.02%, P<0.05), but no significant between-group differences were observed at 6 months (-2.14% vs -1.89%, P=0.90). Changes in glucose and lipid metabolism during the study did not differ significantly between groups.

Conclusions: In CKD patients with type 2 diabetes, dapagliflozin significantly improves proteinuria with short-term eGFR changes as previously reported. The effectiveness of DAPA in reducing uric acid in the real-world experience was observed, while the underlying mechanisms remain to be investigated.

PUB093

Congestive Hepatopathy Caused by Cardiorenal Syndrome Causing Severe Elevations

Swati Viswanathan. *Franciscan Health Inc, Olympia Fields, IL.*

Introduction: 80 year old female presenting with a TIA and heart failure exacerbation with AKI on CKD requiring to be started on ionotrope assisted diuresis to prevent further renal failure. She does not respond to the therapy and also develops sepsis from hospital acquired pneumonia and UTI requiring continuous renal replacement therapy, pressors and intubation for further optimization. The severity of her cardio renal syndrome and cardiogenic shock leads her to develop concomittant congestive hepatopathy leading her to develop severe elevations in her liver enzymes to the level to shock liver or ischemic hepatitis which is a unusual finding.

Case Description: 80 year old female presenting with slurred speech and exertional dyspnea. Admitted for TIA with negative workup of stroke. Patient found to be in a heart failure exacerbation. She has a known medical history of heart failure with reduced ejection fraction with an EF of 20-25% secondary to Takotsubo cardiomyopathy and a clean cardiac cath. She has a CRT-D placed. Patient started on dobutamine assisted diuresis due to severe AKI on CKD III with poor urinary output. Transferred to ICU due to acute metabolic encephalopathy secondary to septic and cardiogenic shock requiring intubation for severe HCAP and a E coli urinary infection. She was required to be placed on a bicarbonate infusion and got CRRT. Due to ongoing cardiogenic shock she developed severe congestive hepatopathy with liver enzymes peaking at AST / ALT of 945/ 590. These levels usually seen in shock liver and unusual in congestive hepatopathy. Pateint also noted to have lupus workup positive. Renal biopsy to rule out SLE nephritis remarkable for findings of diabetic nephropathy and ATN. Patient's renal functions subsequently improved and she was discharged with improved renal outcomes and resolution of her aminotransferases.

Discussion: The takeaway from this unique case of cardiorenal syndrome is the severity of congestive hepatopathy causing significant elevations in aminotransferases. It is very unusual to see such elevations unless it is drug induced, autoimmune or ischemia induced which tells us the severity of her heart failure and her perfusion status. The reason why this happened remains a mystery but it is important to know that it can cause significant elevations in the liver enzymes.

PUB094

Effect of Volume Removal by Hemodialysis on Elevated N-Terminal Pro Brain-Type Natriuretic Peptide (NT-ProBNP) Level

Mohammad Tinawi,[1] Bahar Bastani.[2] *[1]Nephrology Specialists PC, Gary, IN; [2]Saint Louis University, Saint Louis, MO.*

Background: N-Terminal pro brain-type natriuretic peptide (NT-proBNP) is highly sensitive and specific for the diagnosis of congestive heart failure (CHF). Nearly all end-stage kidney disease (ESKD) patients on renal replacement therapy have an elevated NT- proBNP plasma level. Measurements of NT-proBNP before and after hemodialysis (HD) in patients who are hospitalized with volume expansion is a common practice. The purpose of this study is to determine the clinical value of repeated NT-proBNP measurements in patients with ESKD or acute kidney injury (AKI) requiring HD, and to study the effect of volume removal via HD on NT-proBNP level.

Methods: We conducted a retrospective analysis of patients admitted to two community hospitals over a 3-year period (Jan/2020-Dec/2022). Patients with AKI requiring HD or ESKD were screened if they had an admission diagnosis of volume expansion including acute CHF or pulmonary edema that was verified radiographically and by physical examination. Patients with an admission NT-proBNP level and a repeat level 2 to 12 hours after HD were included. Over the 3-year period, 36 patients with ESKD and 5 patients with AKI requiring HD fulfilled the inclusion criteria.

Results: Volume removal via HD had no impact on NT-proBNP levels in ESKD or AKI patients (ESKD P= 0.7858; AKI P=0.6903). Our patients had significantly elevated NT-proBNP due to renal dysfunction and volume expansion. The table below summarizes our main findings.

Conclusions: While identifying acute or chronic HD patients with volume expansion and significant elevation in NT-proBNP to intensify their cardiovascular management may be beneficial, measuring NT-proBNP level after a single HD session to document a positive effect of volume removal is of no clinical value. Our data suggest that NT-proBNP is a useful cardiac biomarker for volume expansion and its elevated level predict high cardiovascular mortality and recurrent hospitalizations in acute and chronic HD patients.

	ESKD (n=36)	AKI (n=5)
Duration of HD in hours (Mean, range)	3.3 (2.5-4)	2.8 (2.5-3)
Volume removal in liters (Mean, range)	2.5 (1-5)	1.3 (1-2)
Number of hospitalizations post initial presentation during the study period (Median, range)	3.0 (0-14)	1 (0-3)
Mortality over the study period (%)	30	60
Pre-HD NT-Pro BNP (pg/ml) (Mean ± SD, range) NT-proBNP calibration range 5 to 35,000 pg/mL	29,151±10,039 (4,113-35,000)	25,823±12,271 (4,270-35,000)
Post-HD NT-Pro BNP (pg/ml) (Mean ± SD, range)	28,980±9,815 (4,440-35,000)	26,523±11,339 (4,736-35,000)

PUB095

Cardiac Dysrhythmia Characterization by Intradialytic Holter Monitoring in Patients with Chronic ESRD

Licurgo J. Cruz. Residencia Medicina Interna HOMS. *Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic.*

Background: Cardiac dysrhythmias are a common complication in patients with end-stage chronic renal disease undergoing hemodialysis. The intradialytic period, during which patients undergo hemodialysis, is particularly vulnerable to developing cardiac dysrhythmias. Intradialytic Holter monitoring is a non-invasive technique that continuously monitors the heart's electrical activity during hemodialysis. The study aims to characterize the different types and frequencies of cardiac dysrhythmias during hemodialysis using intradialytic Holter monitoring. This information could help improve the management and treatment of cardiac dysrhythmias in patients with end-stage chronic renal disease.

Methods: This research corresponds to a descriptive, observational, cross-sectional, primary source study from October 2020 to January 2021. The analysis was conducted using a form divided into four sections corresponding to demographic data, clinical data, laboratory tests, and Holter study reports. The same happens after the participant's agreement and signature of the informed consent.

Results: The results showed that 37.5% of the patients had dysrhythmias recorded on a 24-hour Holter, 55% were between 45 and 64 years of age, and the majority were female, represented by 66.7%. Furthermore, although there was no statistically significant relationship between the duration of dialysis sessions and the number of sessions received per week, it is evident that 88.9% of the patients whose Holter recorded dysrhythmia attended three times per week. The most frequent dysrhythmias recorded were tachyarrhythmias in 41.6%, of which 44% were ventricular.

Conclusions: Although no statistically significant differences were observed, age, sex, and the number of hemodialysis sessions per week are regarded as the group with a predisposition for the presence of dysrhythmias in patients on hemodialysis therapy.

PUB096

Methemoglobinemia in Hemodialysis Patients due to Acute Chlorine Intoxication

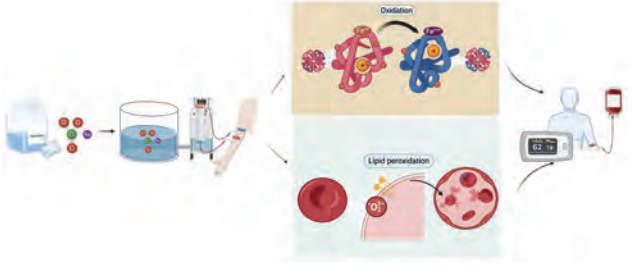
Jonathan Chavez,[1,2] Guillermo Navarro Blackaller,[1,2] Ramon Medina,[1] Maria de la Luz Alcantar Vallin,[1,2] Zarahi Andrade,[1,2] Juárez Correa de León,[1,2] Jorge L. Padilla Armas,[1,2] Rebeca L. Ornelas Ruvalcaba,[1,2] Juan Gómez Fregoso,[1] Edgar J. Carmona,[1,2] César Murguía Soto,[1,2] Jahir R. Camacho.[1,2] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Universidad de Guadalajara, Guadalajara, Mexico.*

Background: Hemodialysis uses municipal water that must be strictly purified and sterilized to be used for that procedure. Large amounts of decontaminants are often used, such as chlorine, and if these compounds are not subsequently removed they can be transferred to the blood of patients causing complications including methemoglobinemia.

Methods: In this case series study dialysis patients in one unit were evaluated. We reviewed clinical characteristics and laboratory findings obtained on the day when the water supply was disinfected with chlorine, with the aim to quantify methemoglobin concentrations. Our objective was to characterize the clinical presentation and management of patients who presented with methemoglobinemia on a specific index day. We also reviewed reported cases in the literature regarding this underreported complication.

Results: Eight patients who presented with chlorine intoxication were evaluated. The methemoglobin concentrations were between 1.3% and 7.9% (reference value 0-1%). We believe this to be caused by water containing 0.78 mg/L of total chlorine. Seven patients presented with cyanosis, 4 with dizziness, 6 with dark brown blood, 4 with dyspnea and 4 with headache and hemolytic anemia. Subjects were treated with supplemental oxygen, methylene blue, intravenous vitamin C, blood transfusions, and increased doses of erythropoietin. No patient died, and all continued with their usual hemodialysis sessions.

Conclusions: Acute chlorine intoxication transferred by the water used during hemodialysis sessions can present with methemoglobinemia accompanied by cyanosis, oxygen desaturation, and hemolytic anemia. Chlorine levels should be carefully monitored in the water used for hemodialysis treatment.



PUB097

Hyperkalemia Prevalence and Recurrence in Chinese Patients on Hemodialysis: A Prospective Multicenter Cohort Study (PRECEDE-K)

Zhaohui Ni,[1] Haijiao Jin,[1] Renhua Lu,[1] Lihong Zhang,[2] Li Yao,[3] Guojian Shao,[4] Li Zuo,[5] Shuguang Qin,[6] Xinzhou Zhang,[7] Qinghong Zhang,[8] Weimin Yu,[9] Qun Luo,[10] Yuqing Ren,[11] Hui Peng,[12] Jie Xiao,[13] Qiongqiong Yang,[14] Qinkai Chen,[15] Yifan Shi.[16] For the PRECEDE-K Study Group. *[1]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [2]The First Hospital of Hebei Medical University, Shijiazhuang, China; [3]The First Hospital of China Medical University, Shenyang, China; [4]Wenzhou Central Hospital, Wenzhou, China; [5]Peking University People's Hospital, Beijing, China; [6]Guangzhou First People's Hospital, Guangzhou, China; [7]Shenzhen People's Hospital, Shenzhen, China; [8]Taihe Hospital, Shiyan, China; [9]Shanxi Bethune Hospital, Taiyuan, China; [10]Hwa Mei Hospital, University of Chinese Academy of Sciences, Ningbo, China; [11]Yangquan Coal Industry Group Co Ltd General Hospital, Yangquan, China; [12]Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China; [13]First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [14]Sun Yat-Sen Memorial Hospital, Guangzhou, China; [15]First Affiliated Hospital of Nanchang University, Nanchang, China; [16]AstraZeneca Investment China Co Ltd, Shanghai, China.*

Background: Hyperkalemia (HK) is a risk factor for cardiac arrhythmia and death in patients with end-stage renal disease (ESRD) on hemodialysis (HD). PRECEDE-K (NCT04799067) was a prospective cohort study that investigated HK burden in Chinese patients on HD.

Methods: Patients aged ≥18 years on HD (≥2 sessions/week) were consecutively enrolled from 15 centers in China and followed up for 24 weeks. Primary and secondary endpoints were the occurrence and recurrence of HK (serum potassium [sK] >5.0 mmol/L), respectively. Risk factors associated with HK occurrence and recurrence were exploratory endpoints.

Results: A total of 600 patients were enrolled (median age: 55 years; 67% male). Most had adequate dialysis at baseline (65% had urea reduction ratio >65%; 75% had Kt/V >1.2). Yet, 453 (76%) patients experienced HK (297 [50%] had sK >5.5 mmol/L and 171 [29%] had sK >6.0 mmol/L; Figure). At 6 months, 356 (79%) of these 453 patients had HK recurrence; 203 (45%) recurred in 1 month and 300 (66%) in 3 months (Figure). HK recurred ≥3 times in 306 (68%) patients and ≥6 times in 161 (36%) patients (Figure). Risk factors for HK occurrence were history of HK, female sex, lower dialysis frequency, and longer dialysis vintage. Risk factors for HK recurrence were history of HK, history of diabetes, and lower dialysis frequency.

Conclusions: HK is common in Chinese patients with ESRD despite standard adequate HD. The high frequency of and short time to recurrence allude to the chronic nature of HK. Effective potassium control on non-dialysis days is recommended in patients on HD, especially those with risk factors, for long-term management of chronic HK.

A Cross-Sectional Study on Outcome of Pro-Brain Natriuretic Peptide (PRO BNP) Levels in Patients on Hemodialysis and Peritoneal Dialysis in a Tertiary Care Hospital

Muhammad Awais,[1,2] Dildar Ahmed,[3] Muhammad Ghaznain,[4,6] Syed Rizwan A. Bokhari.[5] *[1]University Hospital Kerry, Tralee, Ireland; [2]National Rehabilitation Hospital, Dun Laoghaire, Ireland; [3]Prince Sultan Military Medical City, Riyadh, Saudi Arabia; [4]Health Service Executive, Dublin, Ireland; [5]University of Rochester Medical Center, Rochester, NY; [6]Sligo University Hospital, Sligo, Ireland.*

Background: Mean amino-terminal pro-brain natriuretic peptide (NT-proBNP) level has not been studied well in Saudi hemodialysis population and the effect of high flux hemodialysis membrane in comparison to Peritoneal dialysis patients. We aimed to study the significance of NT-pro BNP level in both hemodialysis and peritoneal dialysis subjects.

Methods: This cross-sectional study looked at NT proBNP levels in 50 hemodialysis (HD) patients and 50 patients on Peritoneal dialysis (PD) group in November 2022. Patients in both groups were categorized according to age above and below 70 years. Patients on HD or PD with history of ischemic heart disease or valvular heart disease were excluded from the study.

Results: Among PD patients, 12 patients were above 70 years with mean age of 77.1, while PD patients younger than 70 years comprised of mean age of 41.2 years. We found NT-proBNP 26000 pg/ml in Male patients above 70 years and >12500pg/ml in Females respectively. Similarly those with age less than 70 years had an average NT-proBNP of >17000pg/ml and 25000 pg/ml in male and female subjects respectively. In HD population 26 patients were above 70 years with mean age 73.5 and remaining 24 patients were younger than 70 years of age, with mean age of 50.8. We observed the NT-proBNP levels >5000pg/ml and > 640 pg/ml in Male and female subjects doing PD and HD respectively in older (Above 70) age group. While, younger age group (less than 70 years) had NT-proBNP levels >11000 pg/ml and 8500pg/ml on PD and HD respectively. We found that on average NT-proBNP levels were significantly higher in peritoneal dialysis patients in comparison to hemodialysis patients. No significant difference was found across either gender in both groups.

Conclusions: We hereby conclude that NT-proBNP levels in peritoneal dialysis patients in older age group without any ischemic heart disease, volume overload is high and low in hemodialysis patients due to membrane adsorption effect.

PUB099

Adaptive Dialysis: A New Way of Care in Post-Open-Heart Patients

Armando F. Rodriguez Lopez. *HCA Florida Healthcare, Atlantis, FL.*

Background: Automated adaptive dialysis (AAD) is a system shown to improve tolerance, adherence, clinical versatility and is the backbone of our in-house dialysis machine. The purpose of this quality improvement project is to showcase the performance of the AAD system in post open heart patients.

Methods: A retrospective-observational, chart review study. Database was queried from January 01, 2016, thru December 31, 2022, to include post open heart patients undergoing dialysis via the AAD system in the post-operative stage. Patients undergoing Coronary Artery Bypass Surgery (CABG) and Aortic Valve Replacement (AVR), Mitral Valve Replacement (MVR) and Tricuspid Valve Replacement (TVR) were included.

Results: A total of 30 patients between 42 and 79 years of age, were treated with the AAD system: 73% underwent strict intermittent hemodialysis (IHD) and 27% received a combination therapy (CmT) of either continuous renal replacement therapy, sustained low-efficiency dialysis or slow continuous ultrafiltration. Average body max index was 28.9 and hundred percentage of patients received mechanical ventilation and vasopressor support during the post operative stage. Only patients who received IHD were included in the main analysis since patients on combination therapy had insufficient data recorded and had significant critical illness. Patient characteristics per type of surgery in the main

analysis group consisted of 18 patients post CABG, 1 patient post AVR, 2 patients post MVR and 1 patient with combined CABG/AVR. Ninety percentage of the cohort had history of ESRD and intradialytic complications like clotting only occurred in the CmT group (n:3). Average time of vasopressor support in the main analysis group was less than 24hrs. Key performance indicators are shown on Table 1, while dialysate and blood flow rates ranged between 200-300ml/min and 200-400ml/min respectively. System clotting was prevented by frequent saline flushes instead of heparin flushes except on those patients with complications.

Conclusions: Treatment adequacy with the AAD system in this subset of patients was a safe intervention with adequate performance indicators.

Oral Manifestations, Periodontal Disease, and Need for Dental Treatment in Our Hemodialysis Unit

Isabel Acosta-Ochoa,[1] Manuel Tello-Pellitero,[2] Armando Coca,[1] María Jesús Rollán,[1] Sandra Sanz,[1] Paula Ardura,[1] Carlos L. Merizalde Moscoso,[1] Maria Martinez,[1] Kenia P. Cobo Campuzano,[1] Alicia Mendiluce.[1] *[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain; [2]Universidad Europea Miguel de Cervantes, Valladolid, Spain.*

Background: CKD is associated with specific oral signs and symptoms. Periodontal disease (PDD) is very prevalent in HD individuals, it in turn is related to malnutrition, inflammation, and cardiovascular risk. We evaluated the prevalence of oral manifestations, PDD and need for dental interventions in our HD patients.

Methods: Cross-sectional study of individuals in a HD unit. We analyzed dental features, described the prevalence of oral manifestations, PPD and need for odontological interventions. A dentist performed the dental history and examination. According to his assessment suggested the need for and kind of treatment. All included patients signed an informed consent.

Results: We included 34 individuals, age 62±15, ♂ 77%, HD vintage 48m (6-281). 88% showed absence of dental pieces, 62% had prosthesis. Most frequent oral manifestations were xerostomia 70%, mucosal pallor, whitish tongue, dysgeusia gingival recession (~40%), least frequent bruxism, dental erosion, halitosis, hypersensitivity 6-15% **Table1**. We found 64% of EPD (manifested as calculi and dental pockets) **Table2** and 24% dental caries. The frequency of brushing per day was sometimes 12%, 1x 41%, 2x 32%, 3x 15% **Table3**. 24% were active smokers **Table4**. 65% of patients required some type of treatment, the most frequent being periodontal scaling and dental fillings, >40% required repair or a new prosthesis **Table5**. The frequency of brushing was not positively nor negatively associated with any parameter of PDD or oral signs.

Conclusions: We found a high prevalence of PDD in our HD unit, in accordance with international studies. ~65% of patients require some kind of dental intervention or any action on their prostheses. For this reason, we believe that dental evaluation and treatment should be an integral part of the care of patients in HD. Performing these interventions could improve the parameters of nutrition and inflammation and the quality of life of our patients? Prospective and Interventional studies will be needed to answer this question.

Prevalence of Amputations in Hemodialysis Patients: Dialysis Program Without Socks

Rocio Z. Gonzalez-Marino, Rosa Sanchez Hernandez, Laura Rodriguez Osorio Jimenez, Ana Muñoz Sánchez. *Hospital General de Villalba, Collado Villalba, Spain.*

Background: Dialysis patients are at high risk of ischemia and foot ulcers (14.4%) that frequently precede severe complications, including amputations (5.9%), hospitalizations, and mortality. Critical ischemia in this location accounts for 20% of the annual causes of death in hemodialysis, produces pain that is difficult to control and greatly reduces the quality of life. The aim of this work was to analyze the prevalence and factors associated with amputations in hemodialysis patients, and to assess the evolution after amputation.

Methods: Carrying out a survey by email sent by the SEN (Spanish Society of Nephrology) and SOMANE (Madrid Society of Nephrology). Retrospective, cross-sectional, multicenter study. The survey sent to all hemodialysis units nationwide. Answered by 47 Centers. The exclusion criteria were oncological-traumatic amputations.

Results: 50% of the Units have more than 70 patients 40% diabetics In most Units only 5% of dialysis patients have ulcers 70% of the centers answer that 5% have minor amputations and 5% have more serious amputations 63% of the centers answer that 5% of the patients have more than one amputation Risk factors for amputation: > 60 years, male, diabetes, smoking, hyperphosphatemia, malnutrition, ischemic heart disease In most Units <10% of amputees have been prosthetized Annual mortality in patients with chronic ischemia is 20%. Most of the Units use some diagnostic measure to screen for ulcers and/or chronic ischemia of lower limbs.

Conclusions: Most dialysis units have patients with ulcers in the lower limbs that precede amputations, mortality and dependency. Having amputee patients in the Unit entails reorganization of work and an effort of human and material resources.

PUB102

Not Every ESRD-Hypertension (HTN) Is Missed Dialysis

Tahir A. Jatoi, Sandeep R. Sasidharan, Mohammad W. Abushawer, Syeda S. Bukhari, Subodh J. Saggi, Moro O. Salifu. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: ESRD is defined as eGFR < 15ml/min/1.73m2, along with signs and symptoms of uremia. In US > 500,000 people have ESRD and the number is increasing yearly. One of the common presentations for ESRD in an ED is elevated BP.

Case Description: A 39-year-old AA woman with history of ESRD, uncontrolled HTN with vitreous hemorrhage, MI and CVA with family history of early MI and CVA presented with severe headache and palpitations for two days and had 6 similar admissions for the last one year. Her post-HD BP were noted to be >160/110 and with four antihypertensives. Normal physical exam with vitals stable except for BP of 210/125 without discrepancy in both arms, confirmed with repeat. EKG unchanged with T Inversion in a few leads. Secondary HTN work up initiated for resistant HTN. Labs showed low Dexamethasone <30 mg/ml, Urinary Dopamine <30 mcg, and elevated Aldosterone 42.6 ng/dl, Renin 34.9 ng/ml/hr, normetanephrine 534 nmol/L. Elevated urinary Epinephrine 67 mcg/24 hour, Norepinephrine 436 mcg/24 hour, 24-hour normetanephrine 1041 mcg/24 hour and plasma. CT abdomen showed a 1.4 cm left adrenal mass. Genetic testing revealed paraganglioma with SDHAF2 mutation. 123I-MIBG scan was negative. She is scheduled to go to NIH to have a DOTATE 68 gallium Pet scan for localization and paraganglioma surgery. She continues to be on HD with multiple antihypertensives.

Discussion: Hereditary Paraganglioma Pheochromocytoma Syndrome was diagnosed in our case based on urinary metanephrines and catecholamine levels > thrice the normal value and SDHAF2 mutation. Four distinct syndromes are described with mutation of Succinate Dehydrogenase gene. Our case had PGL type 2 with SDHAF2 mutation. This mutation results in about 95% decrease in flavination of the SDHA and significantly decreases SDH activity. Only few cases of families with SDHAF2 mutation are reported with all the individuals have head and neck paragangliomas only. Pheochromocytomas and paragangliomas are rare neuroendocrine tumors with an estimated prevalence of 1:4500 and 1:1700 and with an annual incidence of 3 to 8 cases per 1 million/year in the general population. Treatment primarily is surgical removal with alpha adrenergic blockade. We present the first reported case of PGL2 with SDHAF2. More studies are needed to find its true prevalence in ESRD population and to be aware not every HTN in ESRD is missed dialysis.

PUB103

Polysulfone Dialyzer Allergy in a Patient on Aquadex Hemofiltration

Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Polysulfone dialyzer allergy is a cause of intractable hypotension, usually occurring within the first 20 minutes of hemodialysis. The treament is to change to a dialyzer made from a different materiel, such as cellulose triacetate. Hemofiltration membranes for the Aquadex system are made of polysulfone. Here we present a case of polysulfone dialyser allergy with Aquadex hemofiltration, preventing the use of this system.

Case Description: An 82 y/o man with CHF, complete heart block, DM, dementia and ESRD was admitted in the CCU for MRSA bacteremia with aortic valve endocarditis and pacemaker lead infection. He was treated with Daptomycin and his pacemaker leads were replaced. He received hemodialysis via a new tunneled catheter. On subsequent treatments his BP was noted to be soft, the next treatment he did not tolerate ultrafiltration and then his dialysis had to be stopped after 50 minutes because of hypotension. The patient was started on Aquadex hemofiltration which was complicated by hypotension with SBP in 80 range with Levophed and Dopamine. The rapid response team was called for itching, facial swelling and dyspnea which was treated with epinephrine, Benadryl and Solumedrol. Aquadex hemofiltration was stopped and BP recovered with albumin. The next day an attempt at hemodialysis was aborted because of hypotension with SBP drop from 120 to 70 range within 20 minutes. A clinical diagnosis of polysulfone dialyzer allergy was made and the following day hemodialysis was performed using a cellulose triacetate dialysis. The proedure and UF were tolerated wthout incident. Subsequent treatments were uneventful and the patient eventually recovered and was discharged.

Discussion: This case shows that polysulfone dialyzer allergy can occur with the Aquadex system, making ultrafiltration impossible despite treatment with steroids, H2-antagonist, epinephrine and vasopressor support. Polysulfone dialyzer allergy is difficult to detect in the critically ill and in patients with heart failure who have multiple possible causes of severe hypotension. This case shows that despite a simpler design, dialysis expertise is valuable for patients using hemofiltration systems.

PUB104

Magnesium in Dialysate: Is Less More?

Nasreen Samad, Cheryl E. Monte. *Barts Health NHS Trust, London, United Kingdom.*

Background: Lower Mg++ levels are associated with increased risk of cardiovascular events in CKD. Higher dialysate Mg of 1 mmol has shown 22% increase in T50 which indicates a higher potency of the serum to inhibit calcification. Recently published study with Magnesium supplementation in CKD did not show slower progression of vascular calcification despite increase in plasma magnesium. It would be helpful to know if patients are at higher risk of low Magnesium level with standard dialysate magnesium of 0.5 mmol/L (1 mEq/L).

Methods: To know the impact of currently used dialysate magnesium on serum Magnesium level in haemodialysis patients predialysis Mg was measured in February 2020, October 2021, November 2022 and May 2023 on all prevalent and incident patients. Dialysate Magnesium was 0.5 mmols/L (1 mEq/L) in all patients. We also measured serum potassium, PTH and phosphate and reviewed medicine intake as Proton pump inhibitors, Calcineurin inhibitors and phosphate binders.

Results: In the years 2020, 2021, 2022 and 2023, Mg level was measured in 124, 93, 99 and 96 patients respectively. Mg level average and range in mmols was 0.944 (0.5-1.4), 0.977 (0.7-1.7),1.004 (0.6-2.1), 1.003 (0.6-2.2) in those consecutive years. Number of patients with Mg level 0.7 or below was 13 (10.4%),3 (3.2%), 3 (3.0%) and 3 (3.1%) in the respective years.

Conclusions: With the current use of standard dialysate magnesium a small number of patients were found to have low Mg, 22 out of 412 (5.3%) on data for 4 consecutive years during measurement of predialysis magnesium in single dialysis unit. After first measurement of serum Mg++ 22.5 % of dialysis patient had died within a year of measurement of Mg level of whom more than half died with COVID-19 in 2020 thus it was difficult to ascertain the impact of serum magnesium on their survival. In following years we found less patients with lower magnesium level. Comaparitively more patients on Proton Pump Inhibitors PPI or Calcineurin inhibitors CNI had lower Mg 14/22 (63%) but the numbers were too small to come to a definite conclusion. In general we did not find a significant impact of dialysate magnesium of 0.5 mmol to increase the risk of hypomagnesimia. Whether increasing dialysate magnesium to increase serum magnesium level have a survival benefit will need to be ascertained by larger and longer term studies. In the mean time standard dialysate magnesium on 0.5 mmol continues to be a safe and acceptable option.

PUB105

Evolution of Clinical Characteristics and Prognosis of Maintenance Hemodialysis Population: A Single-Center Retrospective Study

Xueqin Bian, Li Fang, Hong Ye, Yang Zhou, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To analyze the trends of clinical characteristics of the maintenance hemodialysis (MHD) population in a single center, and to explore the risk factors affecting the survival of MHD patients.

Methods: An epidemiological survey of MHD was carried out in a center of a tertiary hospital from January 1,2009 to December 31, 2018. The original medical records were checked through the HIS and LIS systems. The follow-up endpoints were death, replacement of renal replacement therapy, and transfer to other centers. The trend of clinical characteristics of this population for ten years was observed, and the the risk factors of survival were analyzed using univariate and multivariate COX regression.

Results: A total of 1,509 MHD patients were included. The average age was 63.66±15.21 years old, including 914 males (60.6%) and 595 females (39.4%), and the median vintage of dialysis was 23 months. With the progress of time, the annual number of MHD patients increased from 200 to 915. Diabetic nephropathy has gradually become the primary cause of end stage renal disease. The annual mortality rate decreased from 51.9/1000 person-years to 38.2/1000 person-years, the main cause of death was cardiovascular events, followed by infection. Hospitalization rate was 302/1000 person-years to 405/1000 person-years. The main cause of hospitalization was cardiovascular complications, followed by vascular access-related complications. The COX univariate study indicated that increasing age, DN, hyperphosphatemia, hyperlipidemia, hypoalbuminemia, and central venous catheter were risk factors for death in MHD patients ($p < 0.05$). The COX multivariate study analyzed that increasing age, DN, and TCC use were still risk factors ($p < 0.05$).

Conclusions: The prevalence rate of maintenance hemodialysis in our center increased year by year, and the mortality rate decreased year by year. Aging, diabetic nephropathy, and long-term central venous catheter use were independent risk factors for dialysis patient death.

PUB106

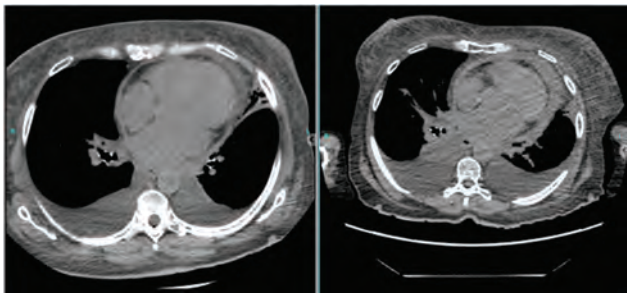
Not the Usual Pericarditis: A Life-Threatening Complication

Gabriel D. Perez Cordero, Juan C. Santiago-Gonzalez, Enrique Leal, Jorge B. Barletta Farias. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Uremia can cause multiple systemic manifestations, including pericardial effusion and pericarditis. Its prevalence ranges from 3%-41%, but in recent decades due to improved treatment, less than 5% develop uremic pericarditis. Below we present a case of a patient with CKD with a rare, life-threatening complication of uremia.

Case Description: Case of a 60-year-old female with stage 4 CKD who presented with shortness of breath, decreased urine output, and chest discomfort. On examination the patient had jugular venous distention, distant heart sounds, tachycardia, decreasing mean arterial pressure, and bilateral lung crackles. Findings were remarkable for anemia, worsening renal function, and azotemia. The patient never developed pulsus-paradoxus or stigmata of cardiac tamponade. Nevertheless, on the serial 2D-ECHO patient had plethoric IVC and evidence of worsening pericardial effusion from small to moderate-large. CT remarkable for pericardial effusion with attenuation indicative of blood products in the space. Findings on echocardiography are presumed to be secondary to uremia. The patient was managed with continuous hemodialysis therapy and blood transfusion. After seven sessions of hemodialysis back-to-back, the patient's clinical condition improved, and the pericardial effusion resolved completely without the need for pericardiocentesis or pericardial window.

Discussion: Hemorrhagic pericarditis is a rare but serious complication of pericarditis and occurs in less than 5% of all cases of pericarditis and confers significant mortality. There is limited specific data available regarding the mortality rate exclusively for hemorrhagic pericarditis in CKD patients but the patient can experience cardiac tamponade, myocardial infarction, and shock. This case highlights the importance of intensive back-to-back hemodialysis therapy along with intensive blood transfusions to the improvement of this life-threatening condition and serial echocardiograms to ensure the resolution of the disease.



PUB107

Efficacy and Safety of Difelikefalin in Treating CKD-Associated Pruritis: A Case Series

Sarayu R. Kalavapalli,[1] Rajani R. Katkuri,[2] Jayasankar K. Reddy.[3] *[1]Coppell High School, Coppell, TX; [2]Falls Kidney, Wichita Falls, TX; [3]Wichita Falls Kidney Clinic, Wichita Falls, TX.*

Introduction: Chronic kidney disease-associated pruritus (CKD-aP) is a prevalent and debilitating condition characterized by moderate to severe itching specifically linked to kidney disease in patients with end-stage renal disease (ESRD). The pathophysiology of CKD-aP remains incompletely understood, but accumulating evidence suggests that it may result from a combination of uremic toxins and instability in the opioid receptor system, particularly antagonistic peripheral kappa opioid receptors. This case series aims to evaluate the efficacy and safety of difelikefalin in treating CKD-aP.

Case Description: We assessed the level of itching in 11 ESRD patients, using the Worst Itching Intensity Numerical Rating Scale (WI-NRS) before and after the administration of difelikefalin (0.5 mcg/kg dry wt.). We recorded patients' baseline characteristics, including age, sex, BMI, time on dialysis, dialysis sessions per week, dialysis duration, and continuation of anti-pruritic treatment. We also documented the quantities of any administered antihistamines, gabapentinoids, topical treatments, narcotics, sedatives, and phosphorus binders and CaXP, Kt/V Urea, PTH and K levels before and during the treatment period. **Results:** Difelikefalin injection significantly reduced the level of itching as measured by WI-NRS scores in 9 out of 11 patients. No serious adverse events were observed, and the known side effects of difelikefalin injection were recorded with consideration to patients' pre-existing health conditions.

Discussion: Our findings suggest that difelikefalin is a safe and effective treatment for CKD-aP in ESRD patients, with no significant adverse effects. However, limitations include relatively small sample size, lack of a control group and short duration of follow-up. Further large scale studies are needed to confirm our results and to determine the optimal dosing and duration of treatment.

PUB108

Association Between Modified Simple Protein-Energy Wasting (PEW) Score and All-Cause Mortality in Patients Receiving Maintenance Hemodialysis in Phramongkutklao Hospital

Narongrit Siriwattanasit. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Protein-energy wasting (PEW) is a frequently observed complication that leads to increased mortality in hemodialysis patients. Many nutritional indexes may be correlated with mortality in these patients. However, a multifaceted assessment of PEW by combined objective nutritional parameters inn Thai population has not yet been established.

Methods: We conducted a single-centered, analytical retrospective study that included 28 ESRD patients receiving maintenance hemodialysis at Phramongkutklao Hospital from January 2020 to December 2021. We calculated modified simple protein-energy wasting (mPEW) from four parameters: Serum albumin and Creatinine level, normalised protein catabolic rate and body mass index. The cutoff values of the modified simple PEW score components were based on receiver operating characteristics curves determined by the Youden index. The sensitivity, specificity, accuracy of mPEW were calculated by independent t-test.

Results: During the 2-year follow-up period, 11 patients died of any cause. The optimal cutoff values of mPEW score to predict mortality in Thai patients is 2, which provided 100% sensitivity, 58.8% specificity and 75% accuracy.

Conclusions: The modified simple PEW score is a useful composite indicator of nutritional status that stratified the risk of all-cause mortality in Thai patients undergoing maintenance hemodialysis.

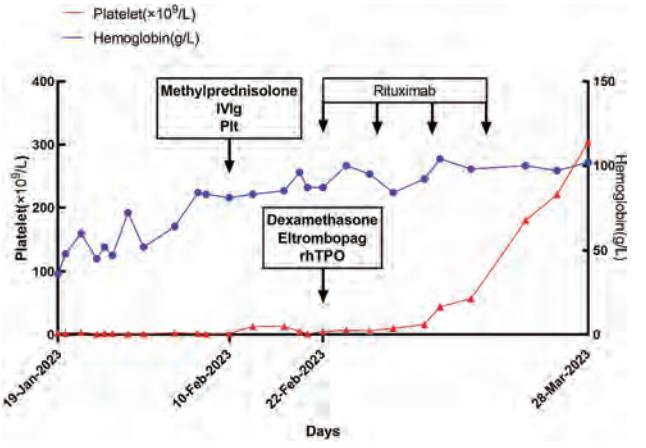
Severe Thrombocytopenic Purpura in a Patient Undergoing Hemodialysis

Shuqin Mei. *Shanghai Changzheng Hospital, Shanghai, China.*

Introduction: Severe acute respiratory syndrome coronavirus (SARS-CoV-2) infection has been a global threat since the end of 2019. Although the main clinical manifestation of coronavirus disease 2019 (COVID-19) are respiratory, its range of clinical manifestation is extensive and may include various systems, including hematological disorders, such as lymphopenia, thrombotic events, thrombocytopenia and immune thrombocytopenic purpura (ITP). A recent meta-analysis and systematic review reported that most of the patients that had developed COVID-19-associated ITP were male and elderly patients. The present paper was the first one that aimed to raise awareness of ITP induced by COVID-19 in patients undergoing maintenance hemodialysis.

Case Description: This is the case of a 75-year-old Asian woman who was diagnosed of COVID-19 positive 15 days before attending to our Emergency Department on January 19th, 2023, with a three-day history of severe bleeding symptoms, including gastrointestinal, mucosal bleeding, epistaxis, and a nadir platelet count of 5×109/L. She had a preexisting medical history of chronic kidney disease for 30 years and treated with maintenance hemodialysis (MHD) 3 times a week since 2012. Platelet count recovery was observed after 45 days of combined treatment with corticosteroids, intravenous immunoglobulin (IVIG), thrombopoietin receptor agonists (TPO-RAs) and rituximab.

Discussion: Hematological consequences of COVID-19 are not uncommon. The mechanism of this manifestation could be changes in bone marrow environment, changes in megakaryocytic differentiation and maturation resulting from infection of hematopoietic stem cells and megakaryocytes, decline in TPO production by liver cells and by the lung damage caused by COVID-19 infection.



PUB110

Epidemiology and Outcomes of Endophthalmitis in Maintenance Hemodialysis Patients: A 5-Year Experience

Srilakshmi Gaddam,[1] Lakshmi Aishwarya Pavuluri,[1] Darshini Kattula,[1] Shaik S. Heera,[1] Jagritee Gupta,[1] Venkata A. Yalamanchili,[2] Siva K. Vishnubotla,[1] Ram Rapur.[1] *[1]Sri Venkateswara Institute of Medical Sciences, Tirupati, India; [2]Dallas Nephrology Associates, Dallas, TX.*

Background: Endophthalmitis is a severe eye infection leading to severe impairment of vision. We would like to present the epidemiology and clinical features of endophthalmitis in maintenance hemodialysis patients in a tertiary referral centre.

Methods: Our institute is a government run tertiary care centre. The department of nephrology conducts more than 72000 dialysis sessions per annum. The demographic features, clinical manifestations, infection focus and visual outcome of the maintenance hemodialysis patients who suffered endopthalmitis from 2017 to April 2023 were recorded.

Results: We observed endopthalmitis in nine patients (0.28%) out of 3206 maintenance hemodialysis patients dialysed at our institute from 2017 to April 2023. The age range was 17 to 74 years (median: 51 years). Most patients presented with ophthalmalgia, periorbital swelling and redness (n = 9, 100%). Blurred vision was reported by seven patients (77.7%) at admission. There were five diabetics and two patients received immunosuppression in the past. The vascular accesses were: untunneled internal jugular catheter in three, arteriovenous fistula in three, tunnelled internal jugular catheter in two and arteriovenous graft in one. Staphylococcus aureus, Klebsiella pneumoniae, Pseudomonas aeruginosa and Acinetobacter were the most frequent causes of bacteremia. Intravenous and intravitreal injections of antibiotics and vitrectomy were performed in all. Only one patient had final vision of 6/20.

Conclusions: This is a large series of patients of endophthalmitis in maintenance hemodialysis patients. Our study showed different pathogen spectrum, different vascular accesses as source of infection and worse visual outcome.

PUB111

Dialysis Disequilibrium Syndrome: A Case of Rapid Overcorrection

Alejandro S. Garcia, Kaltrina Sedaliu. *Bridgeport Hospital, Bridgeport, CT.*

Introduction: Dialysis disequilibrium syndrome (DDS) is a rare, but potentially life-threatening, complication of hemodialysis (HD). It presents as an assortment of neurologic signs with varying severity. It may result in seizures, coma, and even death. Major risk factors include severe azotemia and metabolic acidosis.

Case Description: A 72-year-old male, with no known past medical history, presented with bilateral leg swelling and mild shortness of breath. On presentation he was alert and oriented, examination was remarkable for some asterixis and lower extremity edema. His creatinine level was 24.53 mg/dL, blood urea nitrogen (BUN) 167 mg/dL, and bicarbonate (HCO3) 14 mmol/L. Given metabolic acidosis and volume overload resulting in respiratory compromise, HD was initiated 48 hours after admission. The prescription consisted of blood flow rate of 300 ml/min and dialysis filtration rate of 600 ml/min during 2 hours with no complications during the procedure. Upon completion of his first session, BUN dropped by 50%. He subsequently became encephalopathic. 12 hours later he underwent his second session of HD with same prescription lasting 2.5 hours where

his BUN dropped another 50% and his acidosis was further corrected. Afterwards he developed progressively worsening encephalopathy requiring evaluation for higher level of care. After extensive work up with imaging and laboratory testing for other causes, the diagnosis of DDS was made.

Discussion: DDS is a rare complication of HD occurring secondary to an osmotic gradient that is created by rapid removal of BUN. Other theories include rapid correction of metabolic acidosis and idiogenic osmoles creation. Our case highlights the changes induced by chronic azotemia facilitate the formation of this osmotic gradient. These include increasing aquaporin channels and decreasing urea transporters, which limits the removal of urea even further than its baseline of its normal coefficient of reflection of 0.45 that the urea has (1). Rapid overcorrection of metabolic acidosis, producing a "paradoxical brain acidosis" may also contribute to the genesis of DDS, as this case highlights(2). Management is supportive until homeostasis is restored. Preventative measures include gentle initiation of HD, gradual clearance of urea, and slow correction of acidosis. Adding active osmoles to the dialysate may reduce gradient formation (3).

PUB112

Indications and Complications Associated with Centrifuge-Based Therapeutic Plasma Exchange: A Nephrologist's Perspective

David M. Warner, Manish Anand, Prakash S. Gudsoorkar. *University of Cincinnati, Cincinnati, OH.*

Background: Therapeutic Plasma Exchange (TPE) is an extracorporeal treatment modality used to treat certain diseases, many of which are managed by nephrologists. To investigate the indications and safety of TPE, a retrospective review was conducted to identify the indications and complications of TPE.

Methods: This is a single center retrospective review of centrifuge based TPE managed by the division of nephrology at a tertiary care academic center from June 2018 to July 2022. A total of 1219 TPE treatments in 145 patients were reviewed.

Results: In total, there were 25 diagnostic indications for TPE as outlined in Table 1 with their category of indication as defined by the American Society for Apheresis (ASFA) 2022 guidelines. There were 14 complications associated with TPE which are documented in Figure 1.

Conclusions: Most common being antibody-mediated rejection in kidney transplant recipients (20%), autoimmune encephalitis (16%), and Neuromyelitis optica (11%). 21% of procedures were performed for a condition classified as Category III by the ASFA or not classified. Depletion coagulopathy (48%), hypocalcemia (44%), and hypokalemia (37%) were the most common complications. This study exemplifies the utility of having a systematic audit to review the practice patterns of TPE and supports the inclusion of education on TPE management in nephrology training programs.

Mortality After Gastrointestinal Bleeding Among Dialysis Patients

Belen Alejos,[1] Yue Jiao,[2] Melanie Wolf,[1] John W. Larkin,[2] Anke Winter,[1] Sheetal Chaudhuri,[2] Manuela Stauss-Grabo,[1] Len A. Usvyat,[2] Jeffrey L. Hymes,[2] Franklin W. Maddux,[3] David C. Wheeler,[4] Peter Stenvinkel,[5] Jürgen Floege.[6] On Behalf of the INSPIRE Core Group. *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; [4]University College London, London, United Kingdom; [5]Dept of Renal Medicine Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [6]University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany.*

Background: Gastrointestinal bleeding (GIB) is common in patients on chronic dialysis, yet associated outcomes are uncertain. The INSPIRE group used data on a nationally representative sample of dialysis patients to characterize the mortality rate after a GIB episode.

Methods: We used data on adult dialysis patients treated at a provider network in the United States during Jan-2018 to Mar-2021 who had ≥1 GIB episode. GIB episodes were identified from ICD diagnosis codes recorded as a comorbid condition during dialysis care, or as a discharge reason for hospitalization (Zhao et al., AHRQ 2006). Crude mortality rate was calculated considering death anytime, or 365 days, after the first GIB.

Results: Among a population of 405,530 patients, 31,084 (7.7%) had ≥1 GIB episode. Crude mortality rate any time after the first GIB was 43.7% (n=13,573; **Figure 1A**). Mortality rate after the first GIB comorbidity (40.1%, n=2,435/6,068) was slightly lower than after the first GIB hospitalization (44.5%, n=11,138/25,016). Mortality rate increased with older age and appeared to be highest among patients with an unknown race, followed by a white race (42.3%; **Figure 1B**). Limiting the analysis to the 365 days after the first GIB, mortality rate was 32.2% after any GIB, 19.2% after a GIB comorbidity, and 36.0% after a GIB hospitalization.

Conclusions: Mortality rate after a GIB is high in dialysis patients, with 30% dying within a year and 40% dying anytime during follow-up. Mortality rates were higher after GIB hospitalization versus comorbidity, albeit exceedingly high in both cases. Further analyses are needed and should consider adjustments for age, race, and modality, and comparison to patients who never had a GIB.

Exploring the Management of CKD-Associated Pruritus in Routine Haemodialysis Practice: A Qualitative Content Analysis

Namrata Joshi,[1] James Burton,[1,2] James Medcalf,[3,2] Katherine L. Hull.[1,2]
[1]University of Leicester College of Life Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]UK Renal Registry, Bristol, United Kingdom.

Background: CKD associated pruritus (CKD-aP) is an extremely common symptom affecting up to 68% of patients receiving haemodialysis (HD), and associates with poor outcomes such as reduced quality of life, increased hospitalisation and mortality. However, it is under recognised and undertreated. This study explores current approaches to CKD-aP assessment and management.

Methods: Out-patient letters of prevalent HD patients from the Leicester Renal Network between January 1st and December 31st 2022 were considered. Searches were conducted using terms 'itch', 'pruritis' and 'scratch' plus all derivatives. Qualitative content analysis was conducted (NVivo v1.6.1).

Results: Of the 1085 clinic letters from 389 prevalent HD patients, only 55 mentioned CKD-aP. Braun and Clarke's thematic analysis identified three main themes: responsibility, role of treatment and complexity of CKD-aP. Within the responsibility theme, clinicians were predominantly responsible for management *decisions;* patients, their relatives, and HD staff were responsible for *identifying and monitoring* itch. Treatment was a significant theme throughout. Clinician discussions were almost entirely treatment based. Heterogeneity in approaches between clinicians in managing itch was apparent. Itch is a complex symptom, difficulties in communication were directly linked to non-adherence to treatment. Complexity of CKD-aP was characterised by the interplay of itch with other symptoms. As well as non-adherence, letters often identified the symptom was discussed but then no management plan produced or enacted. Cross cutting all the themes was the significant variability in how itch was identified, addressed, managed, and discussed amongst health care professionals, patients and carers.

Conclusions: There is considerable variation in the assessment and management of CKD-aP. The role of the clinician goes beyond management. Pro-active identification and ongoing monitoring of itch is crucial to successful management and a shared responsibility of all staff, especially as new treatments become available.

PUB115

A Red Herring: Two Simultaneous Cases of Dialysis Effluent Discoloration

Salman Bhutta,[1] Katherine Andrade,[2] Sayed Ali,[3] Mark A. Finger.[1] *[1]Northwell Health, Manhasset, NY; [2]Northwell Health, Forest Hills, NY; [3]Prine Health, Manhasset, NY.*

Introduction: Hydroxocobalamin is a synthetic injectable form of vitamin B12, approved for treatment of cyanide toxicity. A favorable side effect of hydroxocobalamin is a transient elevation in blood pressure, utilized in the setting of vasoplegic syndrome during cardiac surgery. Vasoplegic syndrome manifests with hypotension, increased cardiac index, and decreased systemic vascular resistance. Hydroxocobalamin depletes nitric oxide in vascular endothelium, which helps to reverse vasoplegic syndrome. Hydroxocobalamin, however, can cause reddish discoloration of body fluids interfering with lab colorimetric assays. This can persist for 7-35 days. Hydroxocobalamin's deep red color penetrates the dialysis filter and discolors the dialysis effluent causing false blood leak alarms in the hemodialysis (HD) machines via the machine's photometric sensor. This automatically shuts down the HD machine. An alternative treatment option is continuous renal replacement therapy (CRRT). Blood leak detectors on CRRT machines typically use a single optical emitter which detects light scatter. Therefore, it will not alarm with discolored effluent.

Case Description: Here, we present 2 patients who received Hydroxocobalamin and subsequently developed red effluent. Patient 1 is a 75 yo M with cardiogenic shock having severe mitral regurgitation, and aortic insufficiency (AI). He underwent aortic valve replacement (AVR) and mitral valve replacement. Post-op course was significant for AKI. He was initiated on HD. However, HD was interrupted multiple times due to blood leak alarms that persisted despite changes in the dialysis machine and filter. HD was discontinued, and he was placed on CRRT. Hours later, pt. 2, a 67 yo M with severe AI and severe TR, underwent AVR and TVR. The post-op course was significant for cardiogenic shock with fluid overload. HD was attempted but was terminated due to multiple blood leak alarms. He was also placed on CRRT. On further chart review, pt. 1 received hydroxocobalamin 3 days prior to HD, and pt. 2 received it the day prior to HD.

Discussion: Hydroxocobalamin administration can cause dialysis effluent discoloration. This can lead to the inability to receive HD treatment. Clinicians should be aware of this potential complication and discontinue hydroxocobalamin in HD patients whenever possible. Nephrologists should also be aware of alternative treatment options such as CRRT.

PUB116

Pulmonary Hypertension in Hemodialysis (HD) Patients and Associated HD-Specific Factors: A Retrospective Cohort Study

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: Pulmonary hypertension (PH) is associated with increased mortality and morbidity in hemodialysis (HD) patients. The high incidence of PH in HD patients is not only due to left sided heart disease and HD-specific factors are involved. Mechanisms of PH in HD patients have not been fully understood. This study aimed to evaluate HD-specific factors in PH.

Methods: In a university affiliated dialysis center, a retrospective cohort of ESRD patient under maintenance hemodialysis for at least 3 months followed in dialysis unit. Patients with previous pulmonary embolism, collagen vascular disease, obstructive sleep apnea, chronic obstructive pulmonary disease (COPD), severe mitral or aortic valve diseases, liver failure and heart failure were excluded from the study. A total of 47 patients were included in the study. Echocardiography, Cr and BUN, CBC and electrolyte parameters amd B-type natriuretic peptide (BNP) and proximal and distal AVF in PH group and and non-PH group were examined and their correlation with PASP (Pulmonary arterial systolic pressure) were analyzed. Univariate and adjusted logistic regression analysis were performed to identify the independent associated factors.

Results: Following adjustments in the regression analysis, internal diameters of the left atrium, right atrium, and LVEF were independently associated with PH. There was a positive correlation between access blood flow and PASP. PASP in patients with proximal AVF was significantly higher compared with those with distal AVF. The only laboratory parameter associated was PH was B-type natriuretic peptide (BNP).

Conclusions: PH has a high incidence in ESRD patients under maintenance hemodialysis. The higher level of inflammatory marker BNP suggests a microinflammatory state as an independent risk factor for PH. Left and right atria diameter and LVEF were also independently associated with PH. PASP in patients with proximal AVF was significantly higher compared with those with distal AVF. This study found differences in HD-related factros beween the groups with and without PH.

PUB117

Acute Hemodialysis Rapidly Reverses Cefepime Neurotoxicity

Umair Khan, Sana Fatima, Ann Hinckley, Marat Abdullin, Spencer Hodgins, Gregory L. Braden. *University of Massachusetts Chan Medical School - Baystate Regional Campus, Springfield, MA.*

Introduction: Cefepime-induced neurotoxicity (CIN) is a rare but potentially serious adverse event thought to be due to alterations in γ-aminobutyric acid (GABA) neurotransmission, neurotoxic metabolites, & impaired renal function (S. Lee J of Neurocritical care Vol 12; pp75). Clinical presentation of CIN can range from mild symptoms such as confusion and delirium to more severe symptoms such as seizures and encephalopathy. The best treatment for CIN may be renal replacement therapy (RRT). Herein, we report two cases of severe CIN that were successfully treated with hemodialysis (HD).

Case Description: Case 1 A 65-year-old male with a history of ESRD on iHD, and gram-negative bacteremia due to AV graft infection on cefepime (2gm post HD), developed obtundation, somnolence and unresponsiveness. Entire work for metabolic encephalopathy was negative. Presumed diagnosis of CIN was made and emergent HD resulted in complete resolution of symptoms within 2.5 hours of dialysis. **Case 2** An 85-year-old woman with ESRD and pseudomonas bacteremia on cefepime (2g post HD), was admitted for myoclonus, somnolence and obtundation. Encephalopathy work up was negative. An electroencephalogram (EEG) showed findings consistent with non-convulsive status epilepticus (NCSE). She was started on anti-epileptics and benzodiazepine, however with minimal improvement. NCSE was presumed due to cefepime neurotoxicity and patient underwent emergent HD with improvement in mentation in 3 hours of dialysis. A repeat EEG at 6 hour post HD showed resolution of NCSE.

Discussion: CIN should always be suspected in patients receiving high dose cefepime in the setting of renal failure and encephalopathy. Treatment for CIN primarily involves drug cessation and supportive measures however RRT remains a curative intervention for severe CIN symptoms (seizures, encephalopathy). Hemodialysis removes cefepime from blood rapidly and hastens recovery, especially in life-threatening situations. A single 3-hour HD session efficiently removes 70% - 80% of a given dose (S. Lee J of Neurocritical care Vol 12; pp79). Clinicians should maintain a high index of suspicion in individuals receiving cefepime with diminished renal function. Our cases show that acute hemodialysis effectively reverses CIN. With this we also propose the recommendation for weight based dosing for cefepime to reduce risk of CIN.

PUB118

Membrane Filtration Plasma Exchange Therapy in Nonrenal Diseases and the Participation of the Nephrologist as an Expert in Extracorporeal Therapies

Claudia B. López,[1,2] Pedro Morales Molina,[1,2] Diana Maldonado Tapia,[1,2] Monica Lopez Mendoza,[1,2] Juan D. Diaz Garcia,[1,2] Abel Humberto V. Compean,[1,2] Beatriz R. Cerezo Samperio,[1,2] Julio C. Nieto,[1,2] Pamela Prado,[1,2] Irving G. Ramirez.[1,2] *[1]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico; [2]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico.*

Background: Therapeutic plasma exchange (TPE) is a treatment indicated in multiple diseases with the objective of eliminating high molecular weight plasmatic components that has had favorable results, but in some the benefit is questionable.

Methods: Descriptive, observational and retrospective study of patients with pathologies of non-renal etiology with indication of plasma exchange performed with membrane filtration in a reference medical center from 2016 to 2023.

Results: Data were collected from 16 patients, 50% women, with a mean age of 26.7 years. The indications for performing TPR were 4 due to alveolar hemorrhage, 4 due to thrombotic microangiopathy, 3 due to acute inflammatory demyelinating disease, 2 due to humoral liver rejection, 2 due to acute immune-mediated liver failure, and 1 due to thyroid storm. Systemic autoimmune etiologies were 68.7%, two patients with active humoral

liver rejection, one patient with transverse myelitis, one with multiple sclerosis and one with Guillain-Barré syndrome, 56% presented acute renal failure, of these 77 % required renal supportive therapy. Regarding the prescription, all were performed by membrane filtration (Prismaflex 2000 filter), with replacement fluid with 3% albumin, with a replacement volume of 1.5 in relation to the patient's plasma. Among the complications, the most frequent was hypocalcemia. As outcomes we found that 62% presented complete clinical response.

Conclusions: We found in plasma exchange therapy a safe and effective tool, with main benefit in alveolar hemorrhage and acute inflammatory demyelizing disease since they presented 100% recovery, no favorable response was found in liver disease, among the most serious complications were the infectious processes. The prognosis was good in patients who received plasma exchange.

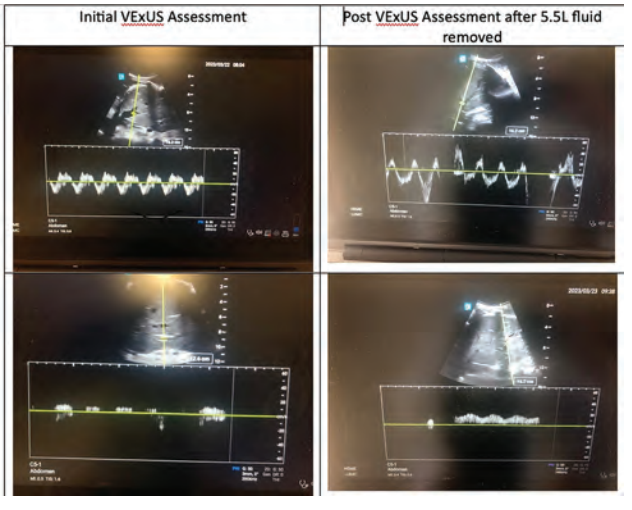
Point-of-Care Ultrasound (POCUS) Venous Excess Ultrasound (VExUS) Score Used for Ultrafiltration Titration in a Patient with Fluid Overload

Sylvester Barnes IV.[1,2] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL.*

Introduction: The patient is a 82YOM with a history of ESRD on MWF renal cell carcinoma with metastasis admitted to hospital after a planned bronchoscopy for biopsy of a lung mass complicated by acute hypoxic and hypercapnic respiratory failure post procedure. The patient required NIV PPV and eventual intubation, with extubation one day afterwards. He received regular HD after extubation with an UF of 1.5L. On hospital day 4 the patient was examined at the end of dialysis with UF of 2.5L performed. The patient still complained of feeling short of breath and "not himself".

Case Description: POCUS was performed at the bedside showing B lines present in all lung fields, and a very dilated plethoric IVC. The significant dilation lead to further examination of the patient's hepatic veins and portal vein. Venus excess ultrasound score provides a sonographic way to evaluate a person for significant venous overload. In this patient he had reversal of his S and D waves in the hepatic veins along loss of continuous portal venous flow resulting in only systolic flow (figure 1). Due to the patients ESRD statues renal vein examination was not performed. Based on his high VExUS score IUF was planned for the following day and had increased UF with HD following this. In total an additional 5.5L were removed over two days with repeat VExUS performed showing less dilated hepatic veins, no longer S and D wave reversal and much some pulsatile portal vein flow remaining but flow that is now continuous. The patient felt significantly less short of breath and felt better overall.

Discussion: In this case POCUS, specifically VExUS, examine along with patient symptoms lead to targeted fluid removal not only until his symptoms improved but also corresponding to sonographic improvement as well. VExUS is an easy tool that can quickly be incorporated for examination of ESRD patients when there is concern for fluid overload and help target more accurate and more accurate UF goal.



PUB120

Predictors and Outcomes of Unplanned Emergency Department Visits of ESRD Patients on Maintenance Hemodialysis in a Tertiary Hospital in Davao City

Phillip Jaynard P. Gatmaitan. *Davao de Oro Provincial Hospital, Montevista, Philippines.*

Background: The incidence of End Stage Renal Disease (ESRD) is high, with Diabetes Mellitus and Hypertension as the leading causes. Statistics showed that it is the seventh leading cause of death among Filipinos with a 10 to 15 percent increase per year and more than 5,000 on renal replacement therapy. ESRD patients on hemodialysis account for 5%-7% of health care expenditures in developed countries. In this study, we aim to determine the factors influencing emergency department (ED) visits among patients with ESRD on maintenance hemodialysis.

Methods: This prospective study included the following: >18 years old and diagnosed ESRD patients on Maintenance hemodialysis.

Results: There were 156 patients included; the mean age was 48.42±14.06, most were males (51.93%) and from Davao City, and have their maintenance hemodialysis in a non-hospital based institution (66.66%). Outcome of this study showed that admission rates were at 87.17%. Odds ratio showed that those that are located outside of Davao city (OR=1.685, P=0.471) and those with Economic status Class D (OR=1.914, P=0.573) got the highest risk associated for admission. For the comorbidities, strongest factor is the presence of Diabetes (OR=5.059, P=0.085) and Hypertension (OR=4.972, P=0.099) and number of resident physician visit of at least a year (OR=2.809, P=0.734) and nephrologists visits of more than eight in a year (OR=1.025, P=0.590) also showed to be a risk factor.

Conclusions: Overall, among the predictors, the strongest risk factors associated with increased risk of admission are patient related factors. These include those that are not from Davao City, Class D socio economic status, comorbidities such as diabetes, hypertension, and congestive heart failure, and lastly nephrologists visit > 8/year and resident physician visit at least 1/year were all identified to have an increased risk for admission. Considering those risk factors, this study showed that admission rates were high and none resulted to death.

PUB121

Evaluation of Triglyceride (TG)/High-Density Lipoprotein Cholesterol (HDL-C) and Non-HDL-C/HDL-C ratios as Mortality Predictors in Hemodialysis Patients of National Medical Center XXI Century

Yessica Lopez Cabrera, Fabiola Pazos Perez, Juan Carlos H H. Hernandez. *Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: The efficacy of triglyceride/high-density lipoprotein cholesterol (TG/HDL- C) and non-high-density lipoprotein cholesterol/ high-density lipoprotein cholesterol (non-HDL-C/HDL-C) ratios had been demonstrated as predictor of adverse cardiovascular events and mortality predictors on healthy patients. However, limited studies have been performed to evaluate the efficacy of TG/HDL-C and non-HDL-C/HDL-C ratios as mortality predictors in hemodialysis patients.

Methods: A longitudinal, retrospective, case-control study was developed. A total of 386 patients with treatment of end stage kidney disease on hemodialysis therapy in Hemodialysis Unit of National Medical Center XXI Century from January of 2019 to December of 2022 were enrolled. The medical records, albumin levels, calcium, hemoglobin, parathyroid hormone (PTH), total cholesterol, HDL-C, LDL-C, triglyceride, TG/HDL- C and non-HDL-C/HDL-C were registered. The odds ratio was calculated using chi-square and student's t-test, considering a $p > 0.05$ as a statiscally significant value. The prognostic values were accessed by univariate and multivariate COX regression analysis.

Results: A total of 386 patients were enrolled. They were distributed as 288 control patients (living) and 98 case patients (dead). The multivariate Cox regression analysis showed that patients over 60 years old (2.19, CI 95%, 1.52-3.17 p <0.001), and a TG/HDL- C index >3.29 were strongly correlated with increased risk of death (1.648, CI 95%, 1.029-2.638, p 0.038). In contrast, the treatment of dyslipidemia was associated with reduction on the risk of death (0.298, CI 95%, 0.160-0.553, p <0.001).

Conclusions: The TG/HDL-C ratio have potential as predictor of mortality in hemodialysis patients. The non-HDL-C/HDL-C ratio failed as prognostic tool, with no statistically significant results in the analysis.

Prevalence of Sarcopenia in a UK Haemodialysis Population

Emma L. Watson, Daniel S. March, Matthew Graham-Brown, James Burton. *University of Leicester, Leicester, United Kingdom.*

Background: Sarcopenia is a characterised by a loss of muscle wasting, reduced muscle strength and low physical performance. Although often associated with ageing, it is now recognised as a complication of other long term health conditions and is associated with worse clinical outcomes including poor quality of life, higher hospitalisation rates and increased mortality. Sarcoenia is cited as a frequent complication of CKD, especially common in people with more advanced disease, but the true prevalence of sarcopenia is unknown. The aim of this study was to determine the prevalence of 'confirmed' and 'severe' sarcopenia in a cohort of UK haemodialysis patients.

Methods: This is a secondary analysis of the CYCLE-HD study cohort, which was a randomised controlled trial assessing the effects of a 6-month intradialytic cycling intervention on cardiovascular health. Presence of sarcopenia was determined using the criteria established by the European Working Group of Sarcopenia in Old People (EWSOP) definition. Sit to stand 5 was used to determine muscle strength, fat free mass index was used ato determine muscle mass and the short physical performance battery to determine physical function. Individuals were classified as either having no evidence of sarcopenia, probable sarcopenia, confirmed sarcopenia, or severe sarcopenia based on the specified cut-offs.

Results: 117 patients (56 ±15 years, 82 [78%] male) were included in the analysis. n=12 patients had probable (10%), n=46 had confirmed (39%) and n=19 (15%) had severe sarcopenia, demonstrating that 63% of our population had some degree of sarcopenia.

Conclusions: The prevalence of sarcopenia that we report here is high. Given the association with poor outcomes and reduced quality of life, it is important to be able to identify those patients with, or at risk of developing sarcopenia to be able to implement effective treatment strategies. Unfortunately, the process of diagnosing this disease is multi-factorial and requires the use of tests that can be expensive and require training. This means that patients are rarely screened, and their sarcopenia status is not recorded. Furthermore, there are currently no validated treatments for sarcopenia. Given the high prevalence in our end-stage renal failure population, there is a clear an urgent need for both better detection and treatment strategies.

PUB123

Improving Transition onto Haemodialysis: A Novel Trainee-Led Clinic

Joseph Cairns,[1] Jennifer Widgery,[1] Clare I. Castledine.[2] *[1]University Hospitals Sussex NHS Foundation Trust, Brighton, United Kingdom; [2]Brighton and Sussex Medical School, Brighton, United Kingdom.*

Background: Starting haemodialysis (HD) is a precarious time with high mortality and worse outcomes in unplanned starts. An audit of our unit demonstrated median time to first consultant clinic review after HD start was 51 days. Two patients died before review and there were 31 emergency admissions within 60 days of HD start. Running an HD unit is in the UK training curriculum. A 2018 survey of nephrology trainees revealed only 40% within 2 years of completion felt, "somewhat/very confident to run an HD unit".

Methods: A trainee led clinic with 1 hour slots 2-3 weeks following in or outpatient HD start was co-designed with patients and the renal MDT. Consultations focused on background, route onto HD, modality choice, vascular access, transplant prospect, medication review, HD adequacy and fluid status exam. Pre-specified data were collected from hospital records and compared with patients starting HD prior to the clinic start using Mann Whitney U tests.

Results: Between Nov 2022 and May 2023 all patients commencing HD (n=47) were seen in the clinic. Patient characteristics (age, gender, ESKD aetiology), route onto HD (planned vs unplanned), modality prior to HD start and dialysis access in use at start were similar to the baseline audit. Time to first review reduced from 51 to 19 days (p=<0.001).

Conclusions: Earlier formal medical review of patients improved time to target weight review, earlier opportunities for referrals to the wider MDT and earlier tailoring of immunosuppression and stop of medications no longer indicated. Trainees gained experience of managing HD patients outside a pager-based, trouble-shooting setting. Future data collection is ongoing to explore reduction in hospital admissions and improvements in trainee confidence in managing HD patients.

	Baseline audit 1/10/21 – 31/3/22 (n=50)	New starter clinic 1/11/22 – 12/5/23 (n=47)
Time to clinic review (median, 1st-3rd IQR)	51 days (30-69)	19 days (14-27)
Trainee ad hoc reviews before 1st clinic	47 (0.94 per patient)	28 (0.6 per patient)

Disaster Preparedness for Climate-Driven Atlantic Hurricanes for Patients Diagnosed with ESKD

Rebecca L. Shakour,[1] Zain Mithani,[1,3] Zelde Espinel,[1,2] Gabrielle Wong-Parodi,[4] James M. Shultz.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Sylvester Comprehensive Cancer Center, Miami, FL; [3]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; [4]Stanford University, Stanford, CA.*

Background: Customized disaster preparedness is a critical unmet need for patients diagnosed with end stage kidney disease (ESKD) who need in-center dialysis. In this current era of compounding disasters, climate change is making Atlantic hurricanes stronger and wetter, with a tendency to stall at the time of landfall, resulting in more powerful, prolonged, and damaging impacts that disrupt in-center dialysis and clinical services for ESKD patients. Surges of airborne diseases complicate hurricane evacuation and sheltering. This complex risk landscape requires tailored approaches to disaster preparedness for patients, clinicians, and dialysis providers.

Methods: We are conducting a literature review on the intersection of ESKD, climate change, hurricane hazards, and disaster preparedness. We devised a qualitative study involving focus groups of ESKD patients and key informant interviews with dialysis providers and nephrologists. We interviewed dialysis providers about their 2022 Hurricane Ian experience. We developed a survey that examines ESKD patients' hurricane threat appraisal, adaptation appraisal, and past hurricane experience. Adaptation appraisal focuses on disaster preparedness, including preparing the household, stockpiling supplies, taking airborne disease precautions, and adding on ESKD-specific preparedness. Patient demographics, assessment of disability, and mental health scales are included.

Results: Based on our interviews, the dialysis center experience during Hurricane Ian was exemplary: among 232 dialysis centers closed for Hurricane Ian, half were operational 2 days post-storm and 230 (99%) were operational 5 days post-storm. We will present key findings from the literature review and the qualitative study, and initial findings from the ESKD patient survey.

Conclusions: Patients living with ESKD who require in-center dialysis have special needs during disasters yet are underprepared for extreme events striking their communities. Layered risks leading to compounding disaster scenarios are increasing in frequency and severity. Compounding disaster risks amplify the urgency for developing effective approaches for safeguarding patients with ESKD, their caregivers, their providers, and their care systems.

PUB125

Lung Ultrasound to Assess Volume Status in Hemodialysis Patients: One-Center Experience

Jorge Sánchez,[1] Haridian Sosa Barrios,[1,2] Irene Martin Capon,[1] Martha E. Diaz,[1,2] Nuria Rodriguez Mendiola,[1,2] Victor Burguera,[1,2] Irene Minguez,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera Gorrin.[1,2] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Instituto Ramon y Cajal de Investigacion Sanitaria, Madrid, Spain.*

Background: Assessing volume status in hemodialysis (HD) is challenging. Misleading dry weight adjustments contribute to intradialytic hypotension or volume overload, with avoidable morbidity and unnecessary expenditure for the healthcare

system. Our objective was to compare lung ultrasound (LUS), bioimpedance analysis (BIA) and physical examination (PE) in volume assessment status in HD patients.

Methods: This is a unicentric, prospective, longitudinal descriptive study. We evaluated volume status by LUS, BIA and PE after the long interdialytic period, predialysis and postdialysis. Data regarding demographics, clinical information, lab tests and HD sessions were recorded.

Results: 9 patients (77.7% male) were included with an average 37±15 months on HD, median age 65±13 years old. Residual renal function was present in 44% of them (> 400 ml only in one), urea-creatinine mean clearance was 3±2.6 ml/min/1,73m2 and 89% had an arterio-venous fistula. Arterial hypertension was present in 78%, diabetes in 33%, ischemic heart disease in 33%, reduced left ventricle ejection fraction in 22% (transthoracic heart ultrasound <6 months) and previous stroke in 22%. Predialysis: 33% showed volume overload signs on PE. Lab test (average): Hemoglobin 11.0 ±0.6 g/dL, urea: 159.4 ±39.8 mg/dL, serum sodium: 139.9 ±1.5 mEq/L and serum potassium: 5.0 ±0.6 mEq/L. BIA: 2.0 ±1.6 L mean volume overload. LUS: mean Frassi Score was 1.7 ±1.0 (normal = 0). Postdialysis: After a mean ultrafiltration of 3.1 ±1.0 L (which represents 4.3 ±1.1 % of the patients' dry weight) with a sodium conductivity of 139.9 ± 1.0 mEq/L, only 2 patients presented transitory intradialytic hypotension. These 2 patients were the ones that presented higher number of B lines in LUS, with no correlation with BIA. 0% showed volume overload signs on PE. Mean Frassi Score was reduced to 0.7±0.7. No dry weight adjustments were needed.

Conclusions: PE showed poor sensitivity for volume status in these patients. LUS was a better predictor of intradialytic hypotension than BIA/PE and constitutes a useful, cheap, innocuous and readily available tool to use in HD patients.

PUB126

Skin Biopsy (SB) in Calciphylaxis: A Must?

Marcos Piris González,[1] Haridian Sosa Barrios,[1] Fernando Caballero Cebrián,[1] Victor Burguera,[1] Cristina Campillo Trapero,[1] Milagros Fernandez-Lucas,[1,2] Maite Rivera Gorrin.[2] *[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Universidad de Alcala, Alcala de Henares, Spain.*

Background: Calciphylaxis is defined by calcification of cutaneous small blood vessels, resulting in ischemic necrotic lesions. It's associated with high mortality, being more common in dialysis patients. Although its diagnosis is mainly clinical, SB the gold standard. However, it has limited sensitivity and is associated with complications such as infection. Imaging tests have been suggested as an alternative diagnostic method, without great success.

Methods: Patients with calciphylaxis between January 2001-February 2023 were included. We evaluated the performance of SB, SB timing, its diagnostic accuracy and complications.

Results: 25 patients were diagnosed, 48% males, mean age of 63.7±14.2 years (range 31-87, median 68). 12 were on hemodialysis, 8 on peritoneal dialysis, 3 were transplanted with functioning grafts and 2 were predialysis. Dermatologists performed 21 SB: 18 first biopsies and 3 rebiopsies (one patient underwent 2 initial biopsies at the same time). The mean time from symptoms onset to SB was 23.8±16.5 days (median 20). In 8 patients, diagnosis was clinical based on characteristic lesions and risk factors. 17 SB were performed on the lower extremities, 3 on upper extremities, and 1 on the abdomen. 76.2% (16) were punch biopsies and 5 were deep spindle-shaped. From first biopsies, 10 (55.5%) were diagnostic, as were the 3 rebiopsies, giving an 61.9% overall diagnostic yield. Time to biopsy was longer in cases where the initial SB was diagnostic (25 vs 22.14 days, p=0.722). All post-SB lesions required wound care, along with calciphylaxis ulcers. Topical sodium thiosulfate, with or without intravenous administration, was used in 4 patients and surgical debridement was performed in 1 patient. Mean wound treatment time was 16.41±13.56 weeks (median 12.14), which was longer in patients with a favorable outcome compared to those who died (21.28 vs 8.48 weeks, p=0.051). Twelve patients developed infectious complications in calciphylaxis lesions (48%), with 8 of them having undergone previous SB (47%). One-year survival rate was 47.8%.

Conclusions: SB is the confirmatory test for calciphylaxis, although it can be inconclusive and associated with complications. Further research is needed to expand our knowledge on the usefulness of imaging techniques, particularly ultrasound considering its availability.

PUB127

Low Parathyroid Hormone (PTH) Is a Risk Factor for Mortality in Incident Patients on Hemodialysis

Hugo B. de Aquino,[1] Maria Eugenia F. Canziani,[2] Ana Beatriz L. Barra,[3] Jorge P. Strogoff-de-Matos,[3] Maria Dalboni,[1] Rosa M. Moyses,[4] Rosilene M. Elias.[1,4] *[1]Universidade Nove de Julho, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Federal Fluminense, Niteroi, Brazil; [4]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: CKD-MBD is a major complication in patients on hemodialysis, contributing to high mortality. We evaluated the role of PTH as a risk factor for mortality in a large cohort of incident patients on hemodialysis.

Methods: 4,317 individuals starting therapy between February 1, 2012, and December 31, 2016, were included. Data evaluated included age, sex, race, diabetes mellitus, body mass index (BMI), paying source (Public Health System or private), place of first dialysis (clinic or hospital), calcium, phosphorus, albumin, urea, alkaline phosphatase and PTH. Patients were divided into 3 groups according to PTH values (<150, 150-600 and >600 pg/mL). Survival analysis was performed using competing risk (kidney transplantation) and censorship for dialysis withdrawal (clinic transfer, change of method or recovery of renal function).

Results: The mean age was 58 ± 16 years, 58.4% men, 43.7% white, 39.7% with diabetes mellitus, 70.9% had their first dialysis session in a hospital, and 59% were financed by the Unified Health System. Median PTH levels were 252 (118-479) pg/ml. The percentage of patients with PTH <150, 150-600 and >600 pg/mL was 32%, 51% and 17%, respectively. Patients with PTH <150 pg/mL were significantly older, mostly white, 47.5% financed by Public Health System, 74% started dialysis in a hospital, had lower BMI, albumin, urea, potassium, phosphorus and alkaline phosphatase, and higher calcium. There were 1,613 deaths in 5 years, of which 423 occurred in the first year. Competing risk analysis revealed that PTH < 150pg/mL was an independent risk factor for mortality (HR 1.14, 95% CI 1.0-1.30, p=0.044) in a multiple-adjusted model in five years but not in a 1-year follow-up (p=0.418).

Conclusions: One-third of patients initiate dialysis PTH <150pg/ml, a population characterized by a lack of private health insurance and laboratory markers suggesting malnutrition. Developing public health policies are needed to minimize the risk of mortality.

PUB128

Holistic Design Philosophy in Dialysis

Clayton Poppe. *Diality, Irvine, CA.*

Background: Medical care is increasingly being pushed to new settings. As dialysis treatments are increasingly conducted at home, in skilled nursing facilities and transitional care units, the requirements on dialysis machines are changing to meet these needs. A more holistic design philosophy is required to balance sometimes competing or conflicting requirements.

Methods: The creation of a design framework starts with a list of the important categories of information. These categories structure information around the challenges we face during product design. For example, how do we think about the tradeoffs between ease of use and flexibility in therapy? The broad categories capture the main design elements we are trying to optimize. Within the broader categories there are more specific attributes or features that make up the major user needs the final device should embody. Once we have created the categories, we organize them in a way that helps highlight how the categories relate to each other; are they opposed or do the overlap? This emerging framework is then used to describe the problems we face and focus ideation on those difficult places where our priorities conflict with each other.

Results: A simple version of the framework that we developed is outlined in Figure 1. The benefit of this framework was to focus early design exploration on the areas that were most in conflict with each other. An iterative process of design, build, test was able to better show the tradeoffs we would need to make to balance our priorities and optimize the design. We know that we can't create something that is all things to all people, so properly exposing and evaluating the tradeoffs between desired attributes allows for a design the holistically meets our requirements.

Conclusions: A framework for understanding conflicting design elements and guiding design at a high level is the best way to balance the many needs and requirements of a complex device.

Preliminary Results of Effective Response to Long-Acting Erythropoiesis-Stimulating Agent (ESA) vs. Short-Acting ESA via IV Route of Administration in Anemia Management

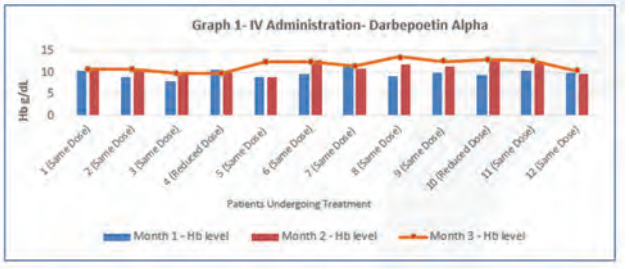
Mercy Chandrabose, Satarupa Gogoi. *HHD Home Healthcare LLC, Dubai, United Arab Emirates.*

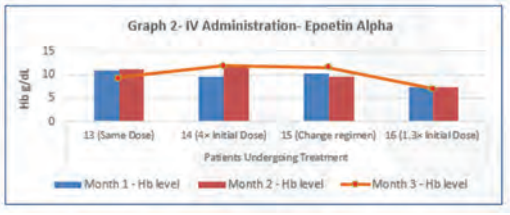
Introduction: The anemia of chronic kidney disease (CKD) is primarily due to insufficient production of the hormone erythropoietin (EPO). Agents that replace EPO plays primary role in treatment of anemia. The subcutaneous route improves the efficiency of therapy, result in reduced dosing requirement (of about 25%) for short acting ESAs, despite patients undergoing hemodialysis in our HHD facility preferred to be treated via IV route, as primary reason is the discomfort with subcutaneous injections. Replacing

short acting ESAs with a longer acting agents provide extended time in circulation to allow the drug to bind to erythropoietin receptors, IV administration of agents with long serum half-life are better choice than Epoetin Alfa.

Case Description: This is a prospective comparative 3 month study on random 16 adult CKD 5D HD patients, treated by Darbepoetin alfa, Epoetin beta (long-acting ESA) & Epoetin alfa (Short acting ESA) weekly to avoid having the Hb concentration fall below (9.0 g/L) were included in this study, average age 58.4 (55-85yr, 70.5% male. Etiology of ESRD was DM in 70%, 60% are Anemic. The serum concentration time profile of medication Aranesp (Darbepoetin alpha) following IV route in CRF patients receiving dialysis were biphasic with a mean terminal half- life of 21 hours which was approx. 3-fold longer than that of Epoetin alfa. Another eg. of Mircera – Epoetin Beta, which has long serum half-life of approx. 5.5 days. The preliminary results of treating anemia by Darbepoetin alfa & Epoetin Beta vs Epoetin alfa via IV route in a special cohort of HD patients shown in Graph 1 & 2.

Discussion: This short study showed, Darbepoetin alfa & Epoetin Beta with long serum half-life via IV route is more efficient in the treatment of anemia than Epoetin alfa thereby eliminating the need for Subcutaneous administration of the drug or increased dose requirement of the medication.





PUB130

Longest Case of Inotropic Support for Cardiorenal Syndrome and Dialysis

James R. Sterrett. *NCH Healthcare System, Naples, FL.*

Introduction: Chronic inotropic use for advanced heart failure and cardiorenal syndrome has been used as an adjunctive therapy at home for those patients. We present an interesting case of a male in his 80s with advanced cardiorenal disease, end-stage cardiomyopathy and advanced chronic kidney disease who survived with a relative quality of life for more than 5 years on continuous infusion of inotropic therapy with dobutamine with hemodialysis TIW.

Case Description: A male in his late 80s with a past medical history of hypertension, diabetes, multifactorial chronic kidney disease, myocardial infarction due to severe obstructive coronary artery disease with subsequent drug-eluting stent placement. This resulted in severe left ventricular dysfunction with an estimated average ejection fraction (EF) 19%. His functional class was III. He underwent cardiac resynchronization therapy and a defibrillator (CRT-D). He was admitted several times for acute decompensated heart failure and on further evaluation he was deemed too tenuous for transplant or destination left ventricular assisted device for mechanical circulatory support. He was recommended to undergo hospice and He was sent home on palliative inotropes with dobutamine at 4 mcg/kg/hr via Peripherally Inserted Central Catheter (PICC) line. Due to advanced chronic kidney disease that failed several diuretic regimens. He continued in outpatient dialysis clinic without significant exacerbations for almost 6 years.

Discussion: Home intravenous inotropic support for palliative reasons has been described in patients with advanced cardiorenal syndrome and end-stage cardiomyopathy not suitable for either transplant or destination therapy such as LVAD. This is to our knowledge, the first reported case of home inotropic use for advanced heart failure that efficiently lasted for more than 5 years. A potential explanation for these long-lasting effects without decompensation is that this patient had a close follow-up with nursing services available throughout the day. During subsequent follow-ups, He did not exert ventricular arrhythmias or required shocks from his defibrillator. Ultimately, he had couple of PICC line infections and sepsis that improved with intravenous antibiotics.

PUB131

Survey of Peritoneal Dialysis Patients' Challenges and Experiences During the COVID-19 Pandemic: A Multicenter Study in the United States

Farah Abifaraj,[1] Dale A. Lee,[2] Meghan E. Lacovara,[3] Tarun Kapoor,[4] Rebecca K. Seshasai,[3] Shweta Bansal,[5] Shuchita Sharma,[2] Jaime Uribarri,[2] Osama El Shamy.[4] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Vanderbilt University Medical Center, Nashville, TN; [5]The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: During the COVID-19 pandemic adjustments were made to peritoneal dialysis (PD) practices in the outpatient units. These unilateral decisions were made by dialysis providers, clinical staff, and governments. The patient perspective regarding these changes during the pandemic has not been explored. We sought to evaluate patient experiences and perceptions of the challenges they faced, institutional adjustments, as well as their mental health during the height of the COVID-19 pandemic in the United States.

Methods: We conducted a cross-sectional survey of PD patients across four home dialysis units affiliated with four large academic centers who were on PD between March 2020 and March 2021.

Results: 98 participants completed the survey across the 4 outpatient PD clinics. Most PD patients did not have to change their home accommodations during the pandemic or have issues getting their dialysis supplies and medications delivered. Most patients felt comfortable coming to the dialysis unit if they needed to during the pandemic. The majority of patients felt supported by their dialysis staff during the peak of the COVID-19 and had modified PHQ-2 and GAD-2 scores not consistent with depression or anxiety. Less than 10% of patients considered changing their dialysis modality.

Conclusions: The adjustments made by the dialysis units during the peak of the pandemic were effective in maneuvering the challenges facing our patients during the COVID-19 pandemic, while providing high quality medical care.

PUB132

Human Factors Testing of the Quanta Dialysis System for Self-Care Hemodialysis in the United States

Kathryn Compton,[1] Michele Gazella,[1] Kelley L. Gorbe,[1] Reid Whitlock,[2] Lisa Bismarck,[1] Paul Komenda.[1] *[1]Quanta Dialysis Technologies Ltd, Alcester, United Kingdom; [2]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: Most hemodialysis (HD) treatments are delivered by healthcare professionals within a facility (in-center HD) but HD is increasingly performed at home via self-care. Uptake of home hemodialysis (HHD) in the United States (US) remains low despite potential improvements in quality of life, health outcomes and cost savings compared to in-center HD. This may be because patients fear they are unable to manage complex treatments at home. With this in mind, the Quanta™ Dialysis System (Quanta Dialysis System) was designed to be more user-friendly. Human factors testing demonstrated the usability of the Quanta Dialysis System in the United Kingdom but has yet to be validated in a US cohort. Using a human factors testing process, we sought to assess how two lay user groups, patients with kidney failure and caregivers, use the Quanta Dialysis System within a representative, simulated use environment in the US.

Methods: We recruited patients with kidney failure and caregivers from a dialysis center in California between June and November 2022. Adults who were a patient on dialysis, or a caregiver for a patient on dialysis, within the last 4 years (including the present) were eligible. Participants trained on the Quanta Dialysis System for 4-5 sessions with a Qualified Nurse Trainer followed by a competency sign off session. After a 48-hour decay period, those deemed competent proceeded to 2 test sessions to perform tasks independently. During testing, independent human factors moderators scored patient performance on 111 critical tasks required to effectively set up, operate, and shut down the Quanta Dialysis System. We assessed the number of participants who passed each task.

Results: A total of 31 individuals (16 patients, 15 caregivers) participated. The mean age was 49 years and 16 (51.6%) participants were female. Of the 16 patients, 9 (56.3%) were from in-center HD. There were 7,200 tasks were tested across all participants. Of these, 96.4% were completed without difficulty, error or assistance.

Conclusions: The Quanta Dialysis System was easy to use after a small number of training sessions and a 48-hour decay period. These results indicate the Quanta Dialysis System has demonstrated a high level of usability in the US and may help improve HHD penetration by using a state of the art, compact, easy to use device.

PUB133

Low Albumin May Be a Predictor of Mortality in Patients Transferred from Peritoneal Dialysis to Haemodialysis

Pranesh Jain, Hari Dukka. *University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.*

Background: Peritoneal dialysis(PD) is a preferred modality for many patients needing dialysis treatment. Most patients on PD either get transplanted, switch to haemodialysis(HD) or die. We did a retrospective, observational study to ascertain the outcomes in patients transferred from PD to HD over a 5-year period and determine variables which may predict poor outcomes.

Methods: Electronic data base was used to obtain data for all patients transferred from PD to HD from 2014-2018. Variables noted were gender, serum albumin, reason for transfer, PD vintage, whether the transfer was expected (commencement of Haemodialysis using arterio venous fistula), as well as Stoke co-morbidity index score(SCI) at the time of transfer. Observed events were infection(pneumonia, cellulitis, line sepsis, tunnel infection or foot infection), morbidity due to vascular disease(peripheral vascular disease, cardiovascular or cerebrovascular accidents) and mortality, within 1 year of transfer to HD. COX regression analysis was used to determine the predictor value for each of the variables for these events.

Results: 95 patients (63 male/32 Female) were transferred from PD to HD in the study period. The mean age was 57.03 +/- 14.22 years, mean serum albumin 24.41+/-6.46 g/dl, mean PD vintage 1.55+/-1.95 years, mean SCI 1.05+/-0.63. The events noted within one year of transfer from PD to HD were death(n=11), vascular events(n=28), infection(n=44). The reasons for switch from PD to HD were infection(62.4%) mechanical causes(12.9%), inadequate dialysis(9.68%), patient's choice(8.6%) and not coping on PD(6.45%).32.3% transfers were expected. COX regression analysis (Table) indicated low albumin was better predictor of mortality post transfer to HD within 1 year of transfer. None of the variables were statistically significant in predicting cardiovascular morbidity or infections.

Conclusions: Patients with low albumin on PD may have adverse outcomes, when transferred to HD**.** Further studies with larger patient numbers are needed to determine outcomes.

Cox regression analysis- predictors for mortality

	HR	Lower 95% CI	Upper 95% CI
Albumin	0.88	0.79	0.99
Stoke co-morbidity Index	1.6	0.66	4.63
Transfer expected	2.58	0.62	10.82
PD Vintage(years)	1.14	0.9	1.44
Age	1.02	0.97	1.07

PUB134

Who Has a Better Kidney-Related Quality of Life: Peritoneal Dialysis or Hemodialysis Patients? A Cross-Sectional Study from Saudi Arabia

Mohammed Alshehri,[1] Abdullah H. Alshehri,[2] Khaled M. Asiri,[1] Mohanad Q. Alshabab,[1] Feras M. Alqahtani,[1] Omar A. Asiri.[1] *[1]King Khalid University College of Medicine, Abha, Saudi Arabia; [2]Saudi Arabia Ministry of Health, Abha, Saudi Arabia.*

Background: ESKD substantially impacts different aspects of patients' lives, including mental and physical health and overall quality of life. The aim of our study is to assess the quality of life (QoL) and the associated predictors in ESKD Saudi Arabian patients receiving either hemodialysis (HD) or peritoneal dialysis (PD). Saudi Ministry of health (MOH) is advancing dialysis care in the country with more focus on patients' satisfaction and QoL. However, the data regarding QoL in Saudi Arabian dialysis patients is limited.

Methods: A cross sectional study was carried out using Kidney Disease Quality of Life scale (KDQOL-36) to assess the QoL. We disturbed a validated formal arabic version of the questionnaire. Patients older than 18-year-old and attending dialysis clinics in Aseer region, Saudi Arabia, were invited to participate in the study.

Results: A total of 152 responses were analyzed, which were separated into two primary groups: the HD group (98 patients) and the PD group (54 patients). Our results showed no significant differences between the two groups except for the physical composite score at which the PD group had a higher mean than the HD group 37.84 vs 44.75, respectively (p <0.001). However, more PD patients reported feeling depressed compared to HD patients.

Conclusions: KDQOL-36 cores were comparable between HD and PD groups except for the physical composite score. On the other hand, PD patients tend to suffer from depression more than HD patients. Interventions to attenuate the physical deconditioning and depressive symptoms in HD and PD patients, respectively, are crucial. Future prospective studies with larger sample sizes are warranted.

Table 1: Comparing Scores Between Hemodialysis and Peritoneal Dialysis

n = 152	Hemodialysis = 98 Mean (SD)	Peritoneal Dialysis = 54 Mean (SD)	p-value
Symptom/ problem list (I1-I12)	64.63 (21.91)	70.8 (18.98)	0.082 a
Effects of kidney disease on the daily life	64.19 (23.52)	67.48 (18.93)	0.380 a
Burden of kidney disease	48.66 [Median: 50.00] (25.98)	47.45 [Median: 46.88] (24.81)	0.657 b
SF-12 Physical Composite #	37.84 [Median: 37.17] (10.21)	44.75 [Median: 41.69] (9.60)	<0.001* b

PUB135

A Review of the Risk Factors and Rates of Peritoneal Dialysis (PD) Peritonitis: A Single-Centre, Retrospective Cohort Study

Stuart R. Deoraj, Ammara Abbas, Bhrigu Raj Sood, Jayakeerthi Rangaiah. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: PD Peritonitis is a frequent and important outcome which contributes to the longevity of the peritoneal membrane and the burden of patient co-morbidities. The existing risk factor data relates to a pool of cohort analyses which are hindered by small numbers of patients included in final analyses. As such, evidence-based indicators against Peritoneal dialysis have not been established.

Methods: This single centre retrospective study pooled all patients who accessed peritoneal dialysis from January 2013 to January 2021 and into two separate groups; those who had microbiological evidence of PD peritonitis vs. those with no evidence of PD peritonitis. Demographic and baseline clinical information was compared between the two groups to provide indicators of peritonitis risk.

Results: A total of 631 patients were included in the final analysis, which included 80 patients with a history of PD peritonitis. A total number of 129 infections were reported in the time frame. The organism most commonly reported was staphylococcus aureus, with 37 infections. The mean age of patients at the time of infection was 60, compared to 55, in their non-infected counterparts (mean difference 4.9 years p = 0.0008). The relative risk of male gender resulting in PD peritonitis was 1.03 (CI 0.75-1.14). Within the infected cohort, the relative risk of Asian and Caucasian ethnicity were reported as 0.62 and 0.56 respectively (CI 0.33-1.8 and CI 0.4-0.77). A total of 28 patients reported recurrent infections. The average age for multiple infections was 63, compared to 57 amongst those with a single infection episode (mean difference 5.8 years CI 0.1). An assessment of the role of diabetes status, serum albumin levels, difficulty rating and method of PD catheter insertion, body mass index along with nasal Staphylococcal Aureus Nasal carriage and patient kt/V, as risk factors for PD peritonitis, is currently underway.

Conclusions: This data demonstrates that in a retrospectively assessed cohort of 631 patients, age was a statistically significant determinant of risk of PD peritonitis, with a predominant staphylococcal organism. Caucasian and Asian ethnicities appeared to have a lower risk of PD peritonitis, but gender was non-significant. Given the retrospective nature of the available data, further investigation is required.

PUB136

Effective Removal of Methylurea by Peritoneal Dialysis

Tanuja Yalamarti,[1,2] Tammy L. Sirich,[1,2] Graham E. Abra,[1,3] Margaret K. Yu,[1] Timothy W. Meyer.[1,2] *[1]Stanford University, Stanford, CA; [2]Palo Alto VAHCS, Palo Alto, CA; [3]Satellite Healthcare, San Jose, CA.*

Background: Peritoneal dialysis (PD) clears different uremic solutes at different rates. The highest peritoneal clearance known to date is that for urea. Because urea is partially reabsorbed in the native kidney as well as rapidly cleared across the peritoneal membrane, PD can control plasma urea levels as residual function is lost. This study examined whether another low molecular weight uremic solute, methylurea, has clearance characteristics similar to those of urea.

Methods: Measurements were made in 9 patients recieving maintenance PD with a weekly stdKt/Vurea of 1.86 ± 0.55 and with variable residual native kidney function (average residual GFR 4.0 ± 3.1 ml/min; range 0 to 9 ml/min). Methylurea, urea, and creatinine were measured in plasma, dialysate, and urine with a new LC/MS/MS assay for methylurea and clearances were calculated using standard formulas.

Results: The time-averaged peritoneal dialytic clearance of methlyurea was the same as that of urea and significantly greater than that of creatinine. The residual native kidney clearance of methylurea was also the same as that of urea with both solutes having residual clearance values less than that of creatinine. This reflected similar native kidney tubular reabsorption of methylurea and urea (fractional residual clearance < 1) in contrast to native kidney secretion of creatinine (fractional residual clearance > 1). The total clearances of the three solutes were similar but peritoneal clearance accounted for a larger portion of the total clearance of methylurea and urea. Mathematical modeling showed that for methylurea and urea current standard PD can provide a time-average clearance of close to 7 ml/min and, presuming no change in solute generation, maintain plasma levels below those seen at the initiation of dialysis as patients become anuric.

Conclusions: The uremic solute methylurea is cleared as rapidly as urea across the peritoneal membrane and its plasma level can be effectively controlled by PD. Other small uremic solutes which share these characteristics remain to be discovered.

Trends and Outcomes in Open vs. Laparoscopic Peritoneal Dialysis Catheter Placement from 2013 to 2018

Ankur Shah,[1,2] Susie L. Hu,[1,2] Christina A. Raker.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Patients receiving dialysis require a durable access to the bloodstream for hemodialysis or peritoneal cavity for peritoneal dialysis. In peritoneal dialysis, the catheter can be placed via a percutaneous or surgical approach, With the surgical approach being open or laparoscopic. The purpose of our study is to demonstrate in the modern era in a nationwide, US cohort the trends and outcomes associated with laparoscopic versus open PD catheter insertion.

Methods: We conducted a retrospective analysis using NSQIP database from January 1, 2013, to December 31, 2018. Patients undergoing peritoneal dialysis catheter placement were identified using relevant Current Procedural Terminology (CPT) codes. Data on patient characteristics, surgical approach and operative characteristics, and perioperative outcomes were extracted. Trends in the proportion of open versus laparoscopic techniques were analyzed over the study period.

Results: A total of 11,732 patients who underwent peritoneal dialysis catheter placement were included in the analysis. The proportion of laparoscopic techniques increased steadily from 76.1% in 2013 to 86.8% in 2018, while the proportion of open techniques showed a corresponding decline. Statistical analysis revealed a significant temporal trend towards a higher utilization of laparoscopic catheter placement ($p<0.001$). Mortality was greater for open insertion compared to laparoscopic (odds ratio (OR) 1.56, 95% Confidence Interval (CI) 1.03 – 2.36, p = 0.04). There was no difference in surgical site infection (OR 1.25, 95% CI .97 – 1.73, p = 0.18), transfusion (OR .89, 95% CI .6 – 1.31, p = 0.55), or sepsis (OR 1.04, 95% CI .67 – 1.6, p = 0.87).

Conclusions: This study provides insights into the temporal trends in open versus laparoscopic peritoneal dialysis catheter placement using a large national database. Our findings indicate a substantial shift towards laparoscopic techniques over the study period. While we found open catheter placement to be associated with higher mortality, we believe this is due to confounding by indication and residual confounding. These findings contribute to the growing body of evidence on the evolving trends in peritoneal dialysis catheter placement and have implications for surgical decision-making and healthcare resource planning.

On Growing Home: A Single-Centre Experience with a Dedicated Peritoneal Dialysis Access Clinic

Shabnam Hamidi,[1,2] Bourne L. Auguste,[1,2] Matthew J. Oliver.[1,2] *[1]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: Growing home dialysis programs has been a priority across Canada over the last decade. Initially a rise in home dialysis rates was observed across the country with initiatives targeting predialysis modality education, the use of transitional care units and increased utilization of assisted home dialysis programs. However, this growth has been challenging to sustain with observed attrition during the COVID-19 pandemic. In 2018, our center established a peritoneal dialysis (PD) access clinic as a means to streamline the process of establishing PD access for patients who had chosen PD as their modality of choice. Herein we describe our center's experience with this dedicated access clinic.

Methods: We reviewed the charts of 29 prevalent predialysis patients who selected PD as their dialysis modality of choice and had an appointment with our PD Access Clinic (PDAC) between March 2021 and November 2022. We collected baseline data including eGFR (mL/min) and risk of progression to ESKD at 2 years' time (as measured by the Kidney Failure Risk Equation) at the time of their appointment, time to PD catheter access and first dialysis modality. We also collected information on unplanned dialysis starts, defined as hemodialysis access placed during hospital admission.

Results: The mean (SD) patient age was 67 (14) years. Patients had an average eGFR of 10 mL/min and KFRE of 64% at the time of their initial PDAC appointment. There were a median of 3 months to PD catheter insertion from their access clinic appointment. Less than half of patients (45%) ended up on PD as their first dialysis modality and 20% of patients had an unplanned dialysis start. 17% remained predialysis at the time of our review.

Conclusions: Dedicated PD access clinics do not ensure preferred dialysis modality. Unplanned dialysis starts occur with a high degree of frequency despite predialysis clinics. Earlier referral for PD access at higher eGFR may increase likelihood of peritoneal dialysis as the initial modality and would be a future area of study.

Comprehensive Peritoneal Dialysis Care Model in a Renal Transplant Program

Enzo C. Vasquez Jiménez,[1] Juan Pablo Ruelas Román,[1] Erwin I. Campos,[2,3] Alfonso Ramos,[2] Sergio O. Hernandez-Ordonez.[2,4] *[1]Hospital Juarez de Mexico, Mexico City, Mexico; [2]Macrotech, Santo Domingo, Dominican Republic; [3]Pontificia Universidad Catolica Madre y Maestra - Campus Santo Tomas de Aquino, Santo Domingo, Dominican Republic; [4]Universidad Nacional Autonoma de Mexico Departamento de Educacion Medica, Tlalnepantla, Mexico.*

Background: Pretransplant peritoneal dialysis (PD) has shown potential benefits, including a reduced incidence of delayed graft function and improved patient survival after kidney transplant. While existing literature does not highlight any significant disadvantages of PD compared to hemodialysis (HD) in the context of transplantation, this study aims to demonstrate the impact of an integral model of care in PD as part of a kidney transplant program for a group of economically disadvantaged patients lacking social security in a third-level hospital in Mexico City.

Methods: An incident cohort of peritoneal dialysis patients was analyzed, who were treated under an integral management model from the beginning of dialytic therapy until kidney transplantation. The integral care model consists of a monthly evaluation by a multidisciplinary team of experts in peritoneal dialysis, who analyze the nutritional, psychological, social, and familial aspects, as well as health education, therapeutic adherence, self-care, hygiene, and aspects related to home therapy. Additionally, nephrological evaluation is included, along with remote monitoring system support for dialytic therapy. Patients over 18 years of age, diagnosed with end-stage renal disease, requiring initiation of renal replacement therapy, and candidates to start a kidney transplant protocol, were included. They were treated at the Nephrology Department of Hospital Juárez de México between June 1, 2022, and March 31, 2023. Descriptive statistics were employed.

Results: A total of 51 patients were included in the comprehensive care model. The characteristics of these patients are presented in Table 1.

Conclusions: The integral model of peritoneal dialysis is a good option for incident patients with the possibility of kidney transplantation.

Effects of Thrice Weekly vs. Home Dialysis on Cardiovascular Functional Capacity (ELDEN) Feasibility Study

Nupur Gupta, Drake Dillman, Gabrielle Kline, Heather Burney, Brent W. Miller, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Conventional in-center thrice weekly hemodialysis (ConHD) regimens are associated with unacceptably high cardiovascular (CV) risk. Given the persistently poor prognosis with ConHD, emerging evidence supports an overarching hypothesis that a more physiological approach to administering dialysis through peritoneal dialysis (PD) or Home Hemodialysis (HHD) may improve outcomes. Our preliminary work has demonstrated that cardiopulmonary exercise testing (CPET) can be used as a robust quantitative probe of impaired CV functional capacity in dialysis patients. The present ELDEN feasibility study sought to assess the feasibility of recruiting PD and HHD patients for comprehensive CPET.

Methods: The ELDEN feasibility study is an ongoing single-center, nonrandomized 3-arm prospective controlled trial comparing HHD, ConHD and PD. Patients in each group were matched by age, gender, and dialysis vintage. All patients underwent breath-by-breath CPET, physical function testing, echocardiography and bioimpedance testing at baseline and 1-year.

Results: A total of n=84 patients to-date (ConHD n=12; HHD n=24 and PD n=48) were screened to-date. N=48 patients met eligibility criteria (ConHD n=8; HHD n=14 and PD n=26), n=28 were have been enrolled to-date (n=7 ConHD, n=8 HHD and n= 13) and n=14 have completed testing (n=6 ConHD, n=8 HHD and n=8 PD patients) to-date(Table 1). There was no difference in age (p=0.7), gender (p=1.0) or dialysis vintage (p=0.2). For CPET, all participants reached a respiratory exchange ratio (RER) > 1.1. No participants experienced an adverse event. Although the study was not powered to detect differences in VO2Peak, there was a trend toward higher VO2Peak in patients on PD (14.5 (12.2, 19.5) ml/min/kg) and HHD (14.6 (12.5, 15.8) compared to ConHD (10.6 (10.0, 14.2) ml/min/kg, P=0.29), Furthermore, VE/VCO2 was highest in patients on HHD compared to PD and ConHD (P<0.01). Additionally, patients on ConHD exhibited reduced peak heart rate compared to those on PD and HHD (P<0.01).

Conclusions: The present study depicts the feasibility of recruitment and performance of CPET in home dialysis patients. Patients on HHD exhibited impaired ventilatory efficiency while ConHD patients demonstrated chronotropic incompetence compared to the other groups.

PUB141

Significant Association of Shared Decision Making on Predialysis Patients with Satisfied Modality Selection and Increased Quality of Life (QOL) After Dialysis

Yasuhiro Onishi,[1] Hiroshi Morinaga,[1] Naoya Kobayashi,[2] Tomoyo Morioka,[2] Ichiro Nojima,[1] Hidemi Takeuchi,[1] Kenji Tsuji,[1] Katsuyuki Tanabe,[1] Haruhito A. Uchida,[1] Hitoshi Sugiyama,[3] Jun Wada.[1] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Okayama Saidaiji Byoin, Okayama, Japan; [3]Department of Medical Care Work, Kawasaki College of Allied Health Professions, Okayama, Japan.*

Background: As the prevalence of kidney failure continues to increase and various patients bear the burden of dialysis, the importance of shared-decision making (SDM) processes is increasing, where health care providers and patients work together to make individualised decisions. Impaired quality of life (QOL) is a serious issue for the patients with kidney failure, but it is unclear whether modality selection and QOL is associated with appropriate shared decision-making.

Methods: We recruited the patients undergoing hemodialysis (HD) or peritonial dialysis (PD) in two dialysis centers between June and December 2022, and surveyed retrospectively regarding their reasons for modality selection, Kidney Disease Quality of Life 36 (KDQOL-36), and 9-item shared decision making questionnaires (SDM-Q-9); based on a 6-point Likert scale that can measure nine concepts related to SDM.

Results: Of 57 participants, with an average age 68.4 ± 14.8 years, 77.2% male and dialysis vintage 2.3 ± 1.7 years, PD patients were 18 (31.6%). The SDM-Q-9 score is significantly higher in PD patients compared with HD patients who received appropriate explanations before initiation of dialysis (Figure). The SDM-Q-9 at the initiation of dialysis in HD patients was positively associated with physical function, social function and role limitations caused by physical or emotional problems at the time of survey, and multiple regression analysis showed a significant association with role/social component summary (P=0.015).

Conclusions: This study has demonstrated that the utilization of SDM process on pre-dialysis patients is significantly associated with appropriate modality selection and better QOL after initiation of dialysis.

Corynebacterium: Too Sticky to Treat Through Peritonitis?

Keziya Mathew, Suzanne G. Martin. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Corynebacterium is an uncommon cause of peritonitis in peritoneal dialysis (PD) with a prevalence of 1.5%. It reportedly responds to antibiotics alone in 60-80% of cases, with a 15% rate of catheter removal (1). We report a case of recurrent Corynebacterium peritonitis ultimately requiring PD catheter removal and transition to hemodialysis.

Case Description: 41M with ESRD on PD developed severe abdominal pain and mild fever. PD catheter exit site and tunnel showed no evidence of infection. WBC was 11,000/uL and PD fluid cell count was 2500 PMN/uL. He was given 2 weeks of IP vancomycin and PD fluid culture was negative. Abdominal pain improved for 6 weeks. Routine post-peritonitis PD fluid WBC count was 143/uL and culture was positive for Corynebacterium species. He was treated with vancomycin for 4 weeks with adequate troughs, but his abdominal pain persisted. PD fluid WBC count was 478 PMN/uL and culture again grew Corynebacterium species. IP vancomycin was restarted but he developed worsening abdominal pain. WBC count rose to 12,300/uL and PD fluid WBC count was 665 PMN/uL. His PD catheter was removed and he began hemodialysis. He completed a 2-week course of IV vancomycin and was transplanted 4 months later.

Discussion: The cure rate of Corynebacterium peritonitis with antibiotics alone was more common compared with S. aureus, Pseudomonas and other gram negatives (2). However, other data suggests that catheter removal may be required more frequently. C amycolatum causes relapsing and refractory peritonitis in children (3), notoriously refractory to antibiotic therapy. Repeat episodes are common even after prolonged quiescence, likely due to biofilm formation, rather than antibiotic resistance. Corynebacterium causes infective endocarditis, mainly in prosthetic valves (4). Patients with C. jeikeium IE more frequently required valve replacement, again suggesting biofilm formation. The rate of biofilm formation in Corynebacterium bacteremia was 46-62% (5). Another study (6) showed the capacity of C.striatum to adhere to abiotic surfaces. Biofilms facilitate pathogen adhesion to foreign surfaces, impeding successful antibiotic therapy. Given the propensity of Corynebacterium species to form a biofilm, treatment may require PD catheter removal at a higher rate than previously recognized.

PUB143

Incidence and Risk Factors for Major Adverse Cardiovascular Events in Peritoneal Dialysis

Catarina Almeida, Vitória V. Paes de Faria, Joana P. Dias, Daniela Lopes, Rute Carmo, João C. Fernandes, Clara Almeida, Ana Marta Gomes. *Centro Hospitalar de Vila Nova de Gaia Espinho EPE, Vila Nova de Gaia, Portugal.*

Background: The high prevalence of cardiovascular disease(CVD) in peritoneal dialysis(PD) is due to traditional cardiovascular risk factors(CVRF), nontraditional factors and dialysis itself. The aim of our study was to assess the incidence of major adverse cardiovascular events(MACE) in PD patients and evaluate risk factors for its occurrence.

Methods: We retrospectively studied PD patients in our unit between January 1st 2015 and April 30th 2022, with a minimum 3-years PD vintage, excluding patients with previous CVD. Data on CVRF, dialysis efficiency, bone mineral disease and PD-related infections was collected. MACE was defined as acute myocardial infarction(AMI), congestive heart failure(CHF), stroke and peripheral arterial disease(PAD).

Results: Of the 43 patients studied, 53.5% were male with a mean age of 56.4±11.8 years. About 98% were hypertensive, 21% diabetic, 19% obese and 54% had dyslipidemia. Twenty-one (48.8%) patients had a MACE after PD initiation. Sex, age, PD vintage and traditional CVRF were similar between patients with and without MACE. The overall incidence rate of MACE was 10.7 events per 100 person-years. Higher calcium level (p=0.028), need of phosphate binders (p=0.046), lower renal Kt/V_{urea} (p=0.034), renal and total creatinine clearance (p=0.038 and p=0.015) were associated with MACE. In logistic regression, higher calcium was an independent predictor of MACE (OR 4.510, CI 95%:1.048-19.415). Nine (20.9%) patients had an AMI with an incidence of 4.6 events per 100 person-years. Cumulative number of peritonitis was an independent predictor of AMI (OR 4.918, CI 95%:1.093-22.132). Eighteen (41.9%) patients developed CHF with an incidence of 9.2 events per 100 person-years. Higher calcium (OR 169.440, CI 95%:2.440-11765.297) and use of sevelamer (OR 54.130, CI 95%:1.272-2302.893) were independent predictors of CHF. Four (9.3%) patients developed PAD and one had

a stroke, with an incidence of 2.04 and 0.51 events per 100 person-years, respectively. There were no predictors for PAD or stroke.

Conclusions: Cardiovascular events rates were high in our PD cohort. Hypercalcemia and hyperphosphatemia, associated with vascular and valvular calcification, were risk factors for MACE and CHF. PD-related peritonitis was a predictor of AMI in our population, in line with previous studies.

PUB144

Partnering for Success: Exploring the Relationship Between Task Distribution and Adherence to Home Hemodialysis (HHD)

Waleed Zafar, Maria Bermudez. *Geisinger Medical Center, Danville, PA.*

Background: Despite several benefits of the more physiologic nature of frequent HHD when compared to in-center hemodialysis, patient and/or care-partner burnout and attrition remains high in HHD with 25 to 40% patients dropping out within the first year (1). Little is known about the degree of patient involvement with specific HHD-related tasks and adherence to therapy. This study aims to assess distribution of HHD-related task burden among patients and care-partners and whether this correlates with adherence to HHD.

Methods: All patients and their care-partners currently enrolled in a single center HHD program were surveyed using PATH-D (2), an instrument that lists 20 HHD related tasks and asks who performs them. We evaluated association between the proportion of tasks a patient reported self-performing with their age, sex, duration on HHD, depression score using patient health questionnaire-9 (PHQ-9) and the number of missed treatments per month.

Results: All 18 patients currently active in the HHD program were surveyed. 9 (50%) patients were female, mean age was 57.8 (range 30-79) and 17 patients did HHD with their spouses. Mean duration on HHD was 552 days (range 83-2058). 12 (66.7%) patients had no missed treatments while 5 had missed a mean of 4 (range 1.5-8) treatments per month. PHQ-9 scores were low (mean 1.3; range 0-3). The proportion of 20 PATH-D HHD related tasks that patients reported self-performing ranged from 0%-90% (mean 32.1%). 43% patients self-cannulated their arteriovenous fistulas. No association was found between proportion of self-performed tasks and demographic characteristics or PHQ-9 scores.

Conclusions: Whether there is an association regarding different patient and care partner task distribution, the type of task and adherence to HHD remains unclear. Even though our ongoing study and early data shows high adherence with nearly 70% patients having no missed treatments within the past three months as well as low depression scores, we observed significant variation in self-performed tasks. Understanding how HHD task distribution impacts adherence to therapy over time can provide a frontier of opportunity for patient empowerment, consideration for retraining to improve ability to self-care, and thereby reduce attrition and burnout.

PUB145

Dialysis-Associated Peritonitis due to Serratia marcescens: A Case Report

Alejandro Toledo Carranza. *Instituto Mexicano del Seguro Social, Cuernavaca, Mexico.*

Introduction: Serratia marcescens (SM) is a Gram-negative, opportunistic, highly virulent bacterium and a rare pathogen that causes peritonitis Case reports, a Canadian case series, and a systematic review in Hong Kong suggested that peritonitis in PD due to SM was associated with high rates of treatment failure and catheter removal We present a clinical case of peritonitis due to SM that led to catheter loss.

Case Description: A 34-year-old man with a history of end-stage renal disease secondary to diabetes on continuous ambulatory PD for 5 years with a history of 2 previous cases of peritonitis with adequate resolution of these and with peritoneal fluid (PF) cultures without microorganism development Admitted for severe abdominal pain, nausea, vomiting and diarrhea in addition to cloudy PF cytology was requested where leukocytes were "uncountable", being 100% polymorphonuclear (PNL), empirically started intravenous ceftriaxone and vancomycin; PF culture was collected where SM was isolated, treatment was continued and cytology was taken again on the third day of treatment finding leukocytes of 1130, being 90% PNL, thinking in adequate response antibiotics were continued for 7 days, however, he presented fever, cytology reporting 3456 leukocytes with 90% of PNL and new culture with isolation of SM again, showing sensitivity to meropenem by meropenem, showing sensitivity to meropenem by meropenem, and the patient was treated with a new culture, She showed sensitivity to meropenem, so it was decided to change the antibiotic, which was effective for 3 days until she presented clinical deterioration and a referral to nephrology was requested, who decided to change to HD and remove the catheter, during the removal she presented purulent material and multiple adhesions, so it was decided that the cavity was not useful and definitive HD; She completed 14 days of treatment with meropenem, presenting improvement and it was decided to discharge her.

Discussion: Peritonitis due to SM is a serious complication, so its surveillance should be intensified and appropriate treatment compatible with the antibiogram should be offered. Low socioeconomic status, poor home environment and hygienic conditions increase the rates of peritonitis due to this pathogen, so more frequent and careful patient and family education in such conditions may improve patient care.

PUB146

Reduced Rate of Peritonitis in Incremental Peritoneal Dialysis (PD) vs. Standard-Dose PD

Javier De Arteaga,[1,2] Pehuén Fernández,[1,2] Walter Douthat,[1,2] Carlos R. Chiurchiu,[1,2] Jorge de la Fuente.[1,2] *[1]Hospital Privado Universitario, Cordoba, Argentina; [2]Fundacion Nefrologica de Cordoba, Cordoba, Argentina.*

Background: incremental PD associates with a reduced rates of infection as compared to standard dose PD. may be related to less manipulation of the PD system but there can be other causes like a better local peritoneal defense resulting from less exchanges. incremental PD is an aything different from standard dose PD:(4 exchanges manual, 2 6lts bags plus a daytime one for APD). **Objective:** to evaluate our results in a retrospective cohort of adult chronic PD patients in a single center analyzing results of peritonitis in both groups: incremental and standard dose PD.

Methods: Patients: 246 adults patients, 53% men, 71.1 % on manual PD and 34.5% incremental. **Study period:** December 1994 to December 2022. Inclusion criteria:chronic PD (3 months) in stable patients with a disconnect double bag system. Peritonitis is according ISPD guide 2016 and causative agents recovered as described previously# (standard culture plaques until 2010 followed by the BACTEC technique plus the Malditof analysis.

Results: See attached tables.

Conclusions: Incremental PD associates to a reduced ner of peritonitis episodes as compared to standard dose PD. Time of followup is significantly lower in Increnmental PD. Kaplan meier (time adjusted) although marking a positive tendency couldn't show a significant reduction in time to the first infection episode for incremental PD. Further prospective studies are needed to answer properly this important question.

Peritoneal Dialysis After Gadolinium-Based Contrast Agent (GBCA) Exposure: A Case Study

Ida A. Ayensu, Kara Kaplan, Khaled Boubes. *The Ohio State University, Columbus, OH.*

Introduction: Nephrogenic systemic fibrosis (NSF) is a disorder characterized by thickening and hardening of the skin overlaying extremities and trunk as well as the expansion of fibrosis of the dermis associated with CD34+ fibrocytes. This rare disorder is only seen in patients with advanced CKD. The most common risk factor of NSF is gadolinium-based contrast agent, (GBCAs). These finding were initially reported in early 2000s when unstable linear GBCAs were given to patients ESKD patients that were dialysis dependent or patients with AKI. Current guidelines recommend dialysis promptly after GBCAs clearance. There is insufficient data on gadolinium clearance with PD. We know that 73-78%, 92-95% and 98-99% of free gadolinium is removed after 1, 2, and

3 HD treatments, respectively. Very few case reports describe limited GBCA clearance with PD. There are no studies on hospitalized patients with high intensity CAPD for gadolinium clearance to guide appropriate therapy, as HD after gadolinium exposure may not be warranted and, thus, could prevent further unnecessary procedures.

Case Description: We had a 49 yo F, on PD for 5 years presented with SDH who had MRI with gadoterate meglumine. She had no other dialysis access other than PD catheter. We prescribed increase frequency of PD exchanges from 4 to 7 exchanges in 24 hours for duration of 48 hours after exposure to GBCA. Serum Gadolinium levels were measured at 0 hours, 24 hours, and 48 hours after exposure. There was a 58% reduction in serum gadolinium levels after 48 hrs. However, we noted that for a variety of reasons, the patient only received 11 (instead of 14) exchanges in 48 hours. Gadolinium level (ng/ml) was [78159] at 0 hrs, [54040] at 24 hrs and [32460] at 48 hrs.

Discussion: The continuous ambulatory PD (CAPD) in this case was less efficient than HD in clearing GBCA. However, this was with a reasonably regular prescription and one would argue that if patient was able to receive 16 exchanges in 48 hours, there is very high probability they could get close to 90% clearance. One study used Automated Peritoneal dialysis (APD) with 10-15 exchanges per day for 24 and 48 hours showed reduction of gadolinium by 90% at 48 hours (Murashima et al). Treatment of patients on PD getting MRI with gadolinium should be tailored to maximize the clearance of GBCA. Further studies on PD and GBCA clearance are needed to establish a better understanding of GBCA clearance.

PUB148

Impact of Dialysis Modality Selection Clinic

Anupkumar Shetty. Dallas Nephrology Associates. *Dallas Nephrology Associates, Dallas, TX.*

Background: President Trump's Executive Order on Advancing American Kidney Health has led to ESRD Treatment Choices (ETC) Model taking effect on January 1, 2021, to promote greater use of home dialysis and kidney transplants for Medicare beneficiaries with ESRD in order to preserve or enhance their quality of care while reducing Medicare expenditures. ETC model and other related models have put tremendous pressure to grow home dialysis programs and Dallas Nephrology Associates (DNA) started 'CKD Modality Selection Clinic' in 2022 to address this. DNA is a single specialty nephrology practice having 110 nephrologists and 15 nephrology offices in Dallas Fort Worth area.

Methods: DNA's CKD Modality Selection Clinic involves a 40 minute visit offered to patients in late stage CKD 4 and CKD 5 before they commit to a dialysis modality. During the initial 20 minutes, they were given a dialysis modality education booklet and were shown a video on dialysis modality education. Subsequent 20 minutes were dedicated to a physician visit involving history taking, focused examination and discussion of certain key elements shown in the video using the demo manequins with PD catheters, demo PD cyclers and demo NxStage machines. An assessment was made regarding dialysis modality selection both by the nephrologist and the patient. Patients were asked to choose a dialysis modality before and after the clinic. Patients were followed by the primary nephrologist and the final ESRD treatment selection was noted when they went on dialysis.

Results: The clinic was started in May 2022 and as of April 2023, clinic has been started in 7 offices. 209 patients have attended this clinic so far. In the pre-clinic questionnaire, 47.8% were uncertain about their dialysis modality selection and post-clinic questionnaire showed that 15.8% were uncertain. As of May 2023, among those who attended the modality selection clinic, 12 patients started home dialysis and 3 started in center hemodialysis.

Conclusions: Modality selection helps people make decision about dialysis modality selection. Educated patients chose home dialysis more often than those who do not take advantage of education.

PUB149

The Technique Failure Frustrating the Road of Intermittent Dialysis to Continuous Ambulatory Peritoneal Dialysis

Mariela Ibarra, Karina Y. Contreras Torres, Jennifer Esquivel, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: When starting peritoneal dialysis in patients with end-stage chronic kidney disease, the biggest challenge is the transition from a modality of intermittent peritoneal dialysis to continuous ambulatory peritoneal dialysis (CAPD).

Methods: A cohort study of patients who started PD in an intermittent modality from September 2022 to May 2023 in the Hospital General de México. Those patients were followed until they met one of the outcomes: starting ambulatory PD, migrating to hemodialysis, or death. We defined technique failure as any outcome that included suspending peritoneal dialysis (migrating to hemodialysis and death).

Results: We included 62 patients, 61% (38) were men, the average age was 49±14 years, 74% (46) had a basic educational level and only 21% (13) had a job. The most frequent comorbidities were hypertension in 92% (57) and diabetes in 58% (36). Urgent dialysis start was present in 68% (42) patients and 85% (49) are economically dependent on their families. Technique failure was presented in 42% (26) of the patients. We found an association between technique failure and unemployment (OR 5.2, 95%IC 1.05-26.3, p=0.04), and with presenting at least one event of peritonitis (OR 15.3, 95%IC 3.8-61.4, p=0.0001). Furthermore, patients with technique failure had a 58% reduction in residual urine output compared with 33% in those continuing dialysis.

Conclusions: There have been a few descriptions about the process faced by patients to achieve an ambulatory PD, especially those who do not have health insurance. In this cohort, we observed that more than 40% of the patients had a failure of the technique before being able to dialyze at home, reflecting a complex adaptation process in patients with limited family support. In addition, it is necessary to facility access to replacement therapy that really improves the quality of life and long-term prognosis.

A Patient with a History of Renal Transplant and a Digit Infection was Found to Have Vascular Insufficiency: A Detailed History and Physical Exam Saved the Patient's Limb

Ali Altayyar,[1] Magdi M. Ibrahim,[2] Ezzat A. Koheif,[1] Khaled A. Al Gahtany,[3] Salhah M. Alajmi,[1] Hossameldin M. Fadulelmula.[1] *[1]Nephrology Section, Department of Medicine, King Khaled Hospital, Almajmaah, Saudi Arabia; [2]Vascular Surgery Section, Department of Surgery, King Khaled Hospital, Almajmaah, Saudi Arabia; [3]Pediatric Department, King Khaled Hospital, Almajmaah, Saudi Arabia.*

Introduction: Steal syndrome is an ischemic phenomenon that can occur as a complication of creating vascular access for hemodialysis. It occurs when blood flow is diverted from the venous side distal to the arterio-venous fistula, resulting in reduced blood supply to the distal tissues.

Case Description: A middle-aged patient who had received a renal transplant 13 years previously was found to have a digital ulcer and was admitted for amputation. After a thorough review and physical examination, the patient was discovered to have an arteriovenous fistula in the same limb; furthermore, there was evidence of steal syndrome. Instead of amputation, the arteriovenous fistula was closed, and the patient recovered spontaneously as blood supply improved.

Discussion: The literature describes some similar cases of ischemic steal syndrome. Our case is unique because the patient presented with ischemic steal syndrome many years after the arteriovenous fistula was no longer in use. In the past, practitioners often asked patients on dialysis about the method of access during the initial examination and immediately considered possible complications. However, when a patient presents with problems that are not located near the access point 13 years after a transplant, this issue can be missed. Furthermore, in our case, the area was covered as the patient had dressed the wound, and the patient did not mention her surgical history during the initial examination. In such cases, the treating practitioner should request consultations from colleagues, take a detailed patient history and ensure that a specialised team conducts a thorough physical examination. Multi-disciplinary team meetings are a cornerstone of patient care. In such meetings, teams cooperate to improve patient care, and every team member works to optimise patient management under the guidance of the leading physician (primary team). Official meetings should be held in all institutions, and meetings can also be called by the lead by the Primary attending Physician/Surgeon. A thorough history and clinical examination is necessary; today, these elements are often under-estimated due to the availability of advanced technology and complex laboratory and radiological investigations.

PUB151

Changes in Catheter Dependence at In-Center Hemodialysis Initiation and During the First Year After Initiation

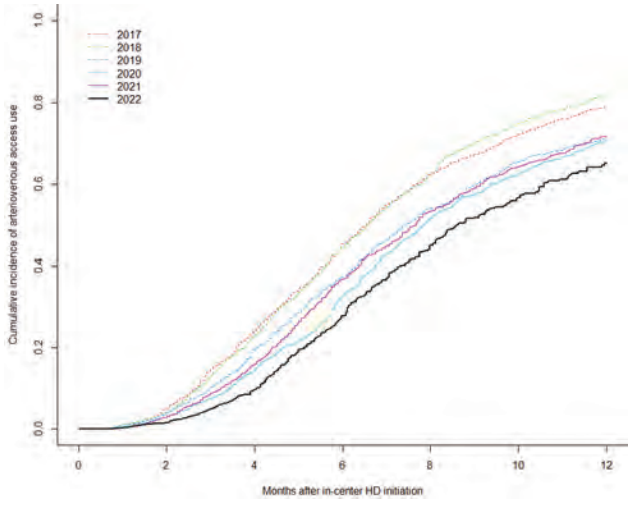
Eric D. Weinhandl,[1,2] Wael F. Hussein,[1,3] Graham E. Abra,[1,3] Gopa B. Green.[1] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.*

Background: The majority of in-center hemodialysis (HD) patients initiate treatment with a central venous catheter (CVC), despite the association of CVC use with poor outcomes, including bloodstream infection. During the coronavirus disease 2019 (COVID-19) pandemic, the prevalence of CVC dependence among HD patients in the US has increased. We investigated whether this trend reflects underlying changes in CVC dependence at initiation and the incidence of conversion from a CVC to an arteriovenous (AV) access.

Methods: We analyzed the electronic health records of Satellite Healthcare, a mid-sized, not-for-profit dialysis provider. From 2012 to 2022, we identified incident end stage kidney disease patients who initiated in-center HD. For each patient, we recorded age, sex, and state of initial dialysis facility. We used segmented linear regression and logistic regression to estimate trends in the prevalence of CVC dependence at first outpatient HD treatment. In the subgroup of patients who were CVC-dependent, we used Fine-Gray regression to estimate trends in the cumulative incidence of conversion to an AV access for ≥6 consecutive HD treatments.

Results: The cohort included 14,764 patients. The prevalence of CVC dependence at HD initiation decreased between 2012 and 2017, reaching a nadir of 79.0%, but increased thereafter, reaching a high of 85.4% in 2022 (adjusted odds ratio, relative to 2019, 1.44; 95% CI, 1.18-1.74). As displayed, the cumulative incidence of conversion from a CVC to an AV access fell initially in 2019, stabilized in 2020 and 2021, and fell again in 2022 (adjusted hazard ratio, relative to 2019, 0.69; 95% CI, 0.61-0.77).

Conclusions: Increasing prevalence of CVC dependence among in-center HD patients has its roots in worsening trends in CVC dependence at HD initiation and during the first year after initiation. These trends emerged before the pandemic, but strengthened in 2022.



PUB152

Nontunneled Hemodialysis Catheter Survival in Uninsured Population in Yucatan, Mexico

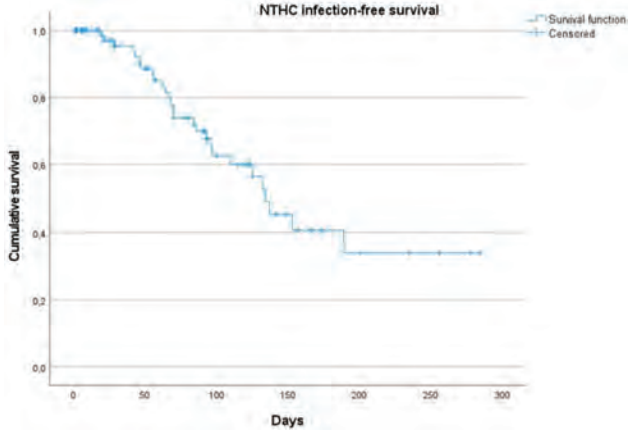
Julio I. Pech Cruz, Leticia M. Tapia Silva. *Hospital General Agustin O'Horan, Merida, Mexico.*

Background: In Mexico, the access to renal replacement therapy (RRT) is unequal, especially for the uninsured. Yucatan has a high prevalence of obesity, diabetes, hypertension, and nephrolithiasis which implies a high burden of chronic kidney disease (CKD). The Hospital Agustin O'Horán receives uninsured patients with CKD from southeast Mexico. In patients who are not candidates for peritoneal dialysis but require RRT with hemodialysis (HD), a non-tunneled hemodialysis catheter (NTHC) is placed. NTHC has a higher rate of infectious complications compared to tunneled hemodialysis catheter (THC) or arteriovenous fistulas (AVF). Our objective was to determine the infection-free survival of NTHC in a low resource setting.

Methods: This is an observational study in patients ≥ 18 years with CKD, who started HD with NTHC in our center from January to December 2022 and evaluated the survival rate of the NTHC related to catheter related bloodstream infections (CRBSI).

Results: 93 NTHC were placed, 63.4% in women, mean age was 49.5 years. Most of the NTHC were non-ultrasound guided (74.2%) and the internal jugular vein was the main insertion site (87.1%). The median survival time until the development of CRBSI was 134 days (95% CI 105.79-162.20). There were no significant differences in catheter survival with respect to sex, age, and insertion site. Compared to the first 30 days after catheter placement, the relative risk for CRBSI was 7.00 (95% CI 2.14-22.87, p= 0.001) within 31-60 days and 7.63 (95% CI 2.36-24.65, p= 0.0007) within 61-90 days.

Conclusions: Long-term catheterization with NTHC is a reality in our center despite the evidence that it poses a high risk for CRBSI. Unfortunately, the lack of a vascular access team for the creation of AVF and placement of THC prevents us to use a more permanent access with less complications. In that sense, we need to engage our policymakers in order to guarantee better vascular access care, especially for the uninsured population.



NTHC infection-free survival

PUB153

Mortality After Arterio-Venous Shunt Creation

Richard E. Wing, Nikhila S. Rao, Nilesh S. Rao, Matthew Wang, Eliane S. Grace, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Arterio-venous shunt (AVS) is the preferred access for most chronic hemodialysis (HD) patients, although placement of AVS induces hemodynamic changes that may be adverse. It is uncertain if echocardiographic findings prior to AVS placement may predict outcomes.

Methods: We conducted a survival analysis on chronic HD patients who were followed by URMC nephrology faculty. We identified subjects who underwent an interpretable ambulatory echocardiogram (echo) <90 days prior to successful AVS creation. Subject characteristics were obtained from the EMR. Echos were re-read for measures of right heart function. Right Ventricular Dysfunction (RVD) is defined as abnormality in any of the following: Myocardial Systolic Excursion Velocity < 9.5 cm/s, Tricuspid annular plane systolic excursion < 17 mm, Right Ventricular Fractional Area Change < 35%, or Right Ventricular Free Wall Strain > -20%. Missing data were imputed as normal. Censoring occurred at transplantation or on 12/31/2022.

Results: Between 1/1/2010 and 12/31/2022, 1319 advanced CKD or ESRD patients under our care underwent at least one echo and/or underwent AVS construction. Thus far, we have identified 38 subjects who received maintenance hemodialysis with an interpretable ambulatory echo <90 days prior to successful AVS creation. Mean follow-up was 1872 ± 1112 days. We tested subject and echo characteristics using the log-rank procedure for association with survival. A multivariate model was constructed using a cox proportional hazards model (table).

Conclusions: In addition to age, abnormalities in right heart function may predict mortality in patients receiving HD who undergo AVS creation. Most subjects in this preliminary group were selected for a related study requiring a second echocardiogram, thus potentially biasing results. Further plans include identifying and adding all eligible subjects from our sampling frame to the cohort.

PUB154

Arteriovenous Fistula Creation Affects the Von Willebrand Factor

Suzanne Laboyrie,[1] Laura M. van der Linden,[1] Roel Bijkerk,[1] Zhuotao Xiao,[1] Laisel Martinez,[2] Roberto I. Vazquez-Padron,[2] Joris I. Rotmans.[1] [1]*Leids Universitair Medisch Centrum, Leiden, Netherlands;* [2]*University of Miami School of Medicine, Miami, FL.*

Background: Von Willebrand Factor (vWF) is a glycoprotein secreted by endothelial cells as high molecular weight multimers (HMWM). VWF mediates hemostasis by platelet binding and factor VIII stabilization. When HMWMs are cleaved into low molecular weight multimers (LMWMs), the capacity to bind platelets is lost. Cleavage of HMWMs is dependent on shear stress and blood flow patterns, such as laminar to turbulent flow transition. Loss of HMWMs can result in increased bleeding tendencies. An arteriovenous fistula (AVF) is the gold standard for hemodialysis access, whereby there is a transition from laminar into turbulent flow at the anastomosis between the artery and vein. In this study, we investigated the effect of AVF flow on the composition of vWF multimers.

Methods: Patient matched plasma samples of two-stage brachiobasilic AVF surgeries were obtained from the Jackson Memorial Hospital and the University of Miami Hospital, according to the hospitals regulatory requirements. ELISAs were performed to determine total plasma vWF concentrations and vWF's collagen-binding capacity. VWF multimers were separated based on molecular weight in a multimer assay and quantified with

densitometric analysis. To eliminate the effect of comorbidities and medication and determine the direct effect of AVF flow on vWF, we used an *in vitro* AVF flow-model.

Results: Plasma samples from patients with end stage kidney failure showed a higher vWF concentration compared to control pooled plasma, and levels remained the same after AVF surgery. No significant reduction in the HMWM over total vWF ratio was observed in the total patient population after AVF creation. However, AVF surgery did result in a 26% reduced capability to bind collagen (p= 0.038). Preliminary data from our *in vitro* AVF flow model indicates a reduction in HMWMs with AVF-mimicking turbulent flow compared to laminar flow.

Conclusions: Decreased collagen binding capacity after AVF surgery indicates a reduction in vWF adherence to the vessel wall. Ongoing experiments in our in vitro AVF flow system will reveal if there is a causal relation between turbulent AVF flow patterns and the reduction in HMWM.

PUB155

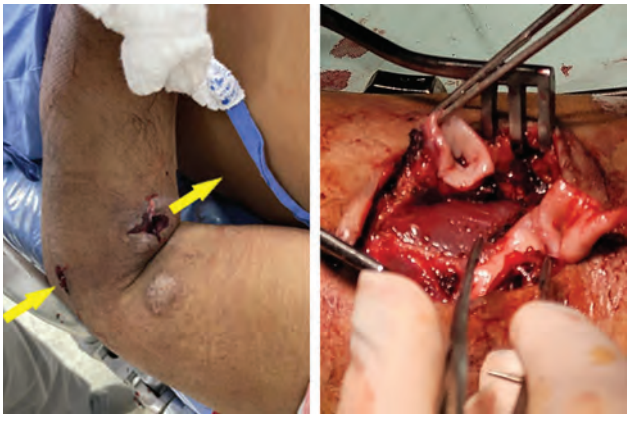
Gunshot Wound in an Arteriovenous Fistula in Hemodialysis Patient

Roberto Ramirez Marmolejo,[1,2] Angélica M. Delgado,[3] Sofia Ramirez Isaza,[4] Carlos Mejia.[2,1] Prevrenal Group. *[1]Universidad del Valle, Cali, Colombia; [2]Fundacion Prevrenal, Cali, Colombia; [3]Hospital Mario Correa Rengifo, Cali, Colombia; [4]Pontificia Universidad Javeriana Facultad de Medicina, Cali, Colombia.*

Introduction: The violence in Cali Colombia has put the medical team in interesting and difficult challenges. The city is in position #24 of the most dangerous in the world. A patient is presented who received an impact from a firearm projectile precisely in his left antebrachial arteriovenous fistula, he was immediately taken to vascular surgery. No articles were found in the literature that presented similar wounds.

Case Description: A 23-year-old male patient, on hemodialysis, was admitted to the emergency, after receiving the impact of a firearm projectile precisely in his left antebrachial arteriovenous fistula. He lost a lot of blood, which was controlled with a tourniquet. He was immediately taken to surgery, finding an aneurysmal degeneration and multiple endothelial lesions proximal to the anastomosis. consequence of the projectile. Image 1. A spindle incision is made over aneurysmal degeneration, Image 2. The fistula is closed and medium-caliber vessels are repaired using the Carrel technique.

Discussion: No articles were found that presented wounds in an arteriovenous fisutula for hemodialysis due to a firearm projectile and only one was found where a self-inflicted stab wound by the patient himself was described as a suicide attempt. the blood flow from an arteriovenous fistula for hemodialysis is greater than 600ml/min, any injury is potentially lethal if not handled properly.



PUB156

Epidemiology of Hemodialysis Vascular Catheter-Related Blood Stream Infections: A Clinical Audit

Dinith P. Galabada, Upuli Kaushalya. *Nephrology Dialysis Transplant Unit, North Colombo Teaching Hospital, Ragama, Sri Lanka.*

Background: Central venous catheters (CVC) are commonly used as a temporary access method for hemodialysis among patients with End Stage Renal Disease (ESRD). Catheter related blood stream infections (CRBSI) are a frequent complication of CVCs. Acceptable incidence rate for CRBSI is <1.5/1000 catheter days according to KDOQI clinical practice guideline for vascular access :2019 update. Therefore, this clinical audit aimed to assess the incidence of CRBSI and associated risk factors.

Methods: Records of ESRD patients undergoing hemodialysis via a CVC at a tertiary care hemodialysis center in Sri Lanka from April 2022 to March 2023 were considered for this audit. Data regarding demographics, medical history, hemodialysis access type (tunneled or non-tunneled central venous catheter), access site (internal jugular or femoral vein), duration of CVC, co-morbidities, development of CRBSI and responsible microorganisms were collected. Age, gender, CVC type, access site, CVC duration and presence of Diabetes mellitus were analyzed to determine the association with CRBSIs.

Results: A total of 76 ESRD patients were analyzed. The mean age was 54.7 (±11.5) years. Majority were male (63.2%). Common co-morbidities were Diabetes mellitus (72.4%) and hypertension (73.8%). In most patients, (81.6%) diagnosis of chronic kidney disease was made after ESRD developed. No previous nephrology clinic follow up, before initiation of hemodialysis, was observed in 44 (57.9%) patients. Median catheter duration of non-tunneled CVCs (NTCVC) (n=49) was 16 days and tunneled CVCs (TCVC) (n=71) was 144 days. NTCVCs had a CRBSI incidence rate of 7.07/1000 catheter days while TCVCs had a considerably low-rate of 0.58/1000 catheter days. Causative microorganisms were *Staphylococcus aureus* (31.6%) including Methycillin resistant variant, Coagulase negative *Staphylococcus* (23.07%) and *Klebsiella pneumoniae* (15.3%). Age, gender, Diabetes mellitus, site of CVC and duration of CVC showed no significant associations with CRBSIs.

Conclusions: Tunneled CVCs CRBSI incidence is within the acceptable range despite having longer catheter durations, while NTCVCs show a higher CRBSI incidence than the target value. Our analysis did not discover any significant associations with CRBSI incidence. Therefore, we recommend changing access from NTCVC to TCVC or arteriovenous fistula at earliest convenience to prevent CRBSI.

PUB157

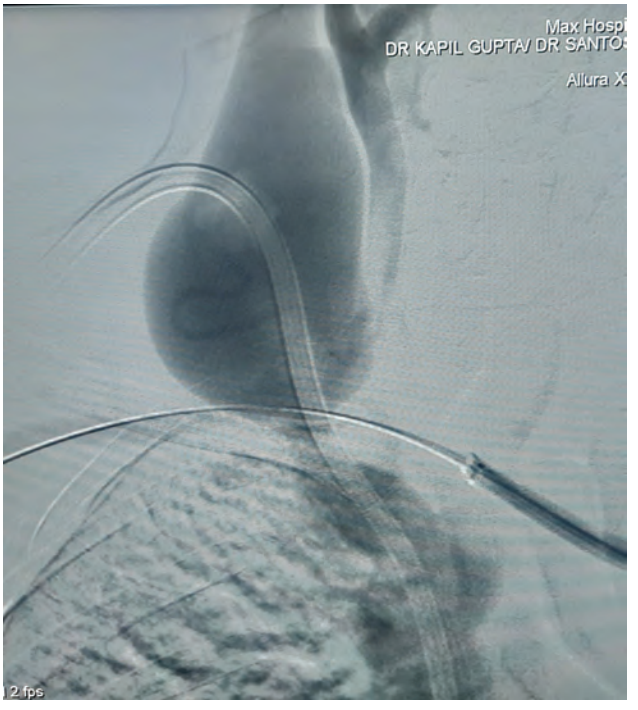
A Rare Complication of Traumatic Arteriovenous (AV) Fistula Creation Between Right Subclavian Artery (SCA) and Right Internal Jugular Vein (IJV) After Right IJV Permcath Insertion

Anil K. Jhajhria, Lovy Gaur, Manisha Dassi, Manoj Singhal. *Max Super Speciality Hospital Vaishali, Ghaziabad, India.*

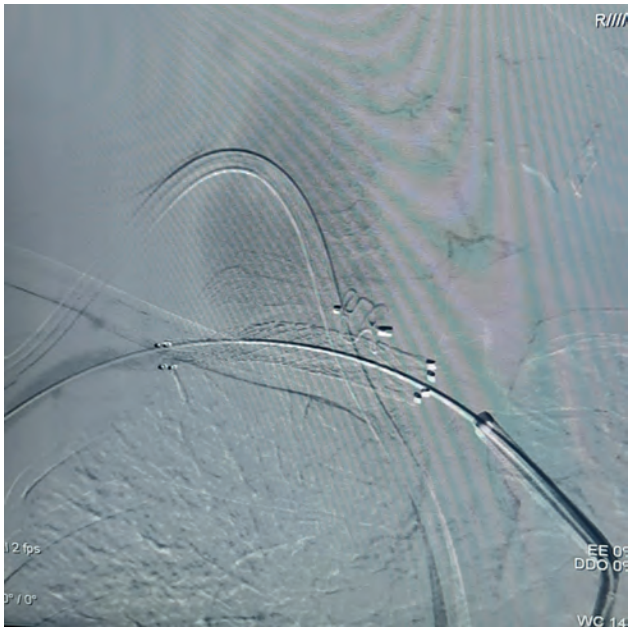
Introduction: Interventional Nephrology (IN) is emerging as a subspecialty which has a lot of potential to grow.

Case Description: 59 years female, case of chronic kidney disease stage 5 on maintainence haemodialysis (MHD) via right IJV permcath got admitted with fluid overload. On examination, a continous thrill was felt in the neck at the site of permcath insertion. After stabilisation, she was taken for peripheral angiography, angioshot from right femoral artery (RFA) showed large tract leading to AV fistula between right SCA & right IJV. In the same sitting, vascular plug through RFA long sheath passed & deployed in the tract. Covered stent deployed at the origin of right SCA & ballon expansion done. Two coils deployment done but due to high flow through AV fistula, coils were dislodged into pulmonary artery which were later snared out. Post procedure check angiogram showed drastically reduced flow through AV fistula & clinically thrill disappeared.

Discussion: This case showed successful treatment of traumatic AV fistula with angioplasty, highlighting the importance of IN in management of vascular access associated complications.



AV fistula



Post Angioplasty

PUB158

Unconventional Ultrasound (US)-Guided CVC Placement

Madeline S. Chung, Marie Fouad, Khaled Boubes. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Percutaneous canulation of central veins is used for both short and long-term vascular access (VA). VA is an area of difficulty among KRT patients who have had multiple procedures involving the central veins. These patients are prone to vascular calcification, stenosis and thrombosis related to their VA, complicating further VA planning and procedures. This is especially true in emergencies when expedient bedside placement of dialysis access is necessary, but difficult using conventional methods.

Case Description: 60 yo man with ESKD on HD via LUE AVF who presented with worsening dyspnea admitted for CHF and pulmonary hypertension management complicated by septic shock requiring initiation of CRRT via catheter. The left internal jugular vein was the only access option. Confirmatory CXR showed the catheter with the tip overlying the right brachiocephalic vein (BCV) near the superior vena cava (SVC) confluence. Two further attempts at placement in the LIJ vein resulted in similar positioning. He was unstable for transport to IR. We placed a guidewire into the malpositioned LIJ catheter and retracted it. The ultrasound (US) probe was placed at the base of the right neck to visualize the right subclavian arch (opposite the insertion site) and guidewire, which was retracted out of the right BCV. The wire was advanced without visualiztion in the right subclavian arch, leaving the SVC as the default location, since its location deep in the thoracic cavity, precludes visualization of the SVC by US.

Discussion: CVC can be a difficult procedure especially when approached via the LIJ vein due to its tortuous path. It is further complicated in patients with difficult anatomy. At most institutions, bedside resources for image guidance are still largely limited to US and CXR, and are generally the only option in patients too ill for transport to the radiology department where more advanced options are available. It is therefore important to utilize the bedside US to its full capacity and learn different windows to visualize VA options beyond the conventional approach.

Malpositioned LIJ CVC in the right BCV

PUB159

The Impact of the Infecting Organism on the Outcome of Tunneled Dialysis Catheter-Related Bloodstream Infections: A Single-Center Record

Petros Kalogeropoulos, Ourania Tsotsorou, Ioanna Tsoumpou, Konstantinos Gkiolas, Petros Nikolopoulos, Sophia Lionaki. *Department of Nephrology, 2nd Propaedeutic Internal Medicine, Medical School, National and Kapodistrian University of Athens, "Attikon" University Hospital, Athens, Greece.*

Background: Tunneled double-lumen catheters are increasingly used as permanent vascular access in hemodialysis patients. Catheter-related bloodstream infection (CRBSI) is a major cause of hospitalization with increased mortality and cost. The purpose is to study the effect of the pathogen on the clinical course of the hemodialysis patients with CRBSI.

Methods: Patients hospitalized in our department from 11/2021 to 12/2022 with established CRBSI were retrospectively studied. Their demographics, duration of hospitalization, microbiological data, central venous catheter management and hospital outcome were recorded.

Results: A total of 27 patients with median age (SD) 68,03 (16,93) years were treated, 12 (44.4%) were men. The following pathogens were isolated from the blood cultures: Staphylococcus aureus in 7 (25.9%) patients, coagulase-negative Staphylococcus in 10 (37%) patients, Gram-positive bacteria in 4 (14.8%) patients, Gram-negative bacteria in 3 (11.1 %) patients, candida in one (3.7%) patient, while 2 (7.4%) patients had negative cultures. Mean (SD) duration of hospitalization was 16,85 (13,15) days for all patients. Patients in whom Staphylococcus aureus and Candida were isolated had longer hospital stay than other infections with a mean (SD) 29 (18) days and 41 days respectively (p=0.014). Metastatic infections occurred in 4 (14,8%) patients, of whom 2 had endocarditis, one endocarditis and pulmonary abscess, and one endocarditis, lung abscess and brain abscess. All 4 patients isolated Staphylococcus aureus in blood culture out of a total of 7 (57,1%) patients with this pathogen (p=0.02). 3 of 7 (42,8%) patients with Staphylococcus aureus, 1 of 10 (10%) with coagulase-negative Staphylococcus, and 1 of 3 (33,3%) with Gram-negative bacteria died (p=0.385). In 26 of the 27 patients (96.3%) central venous catheter was removed.

Conclusions: The majority of patients in the present sample required central venous catheter removal. The type of pathogen seems to play an important role both in the duration of hospitalization and in the occurrence of metastatic infections.

PUB160

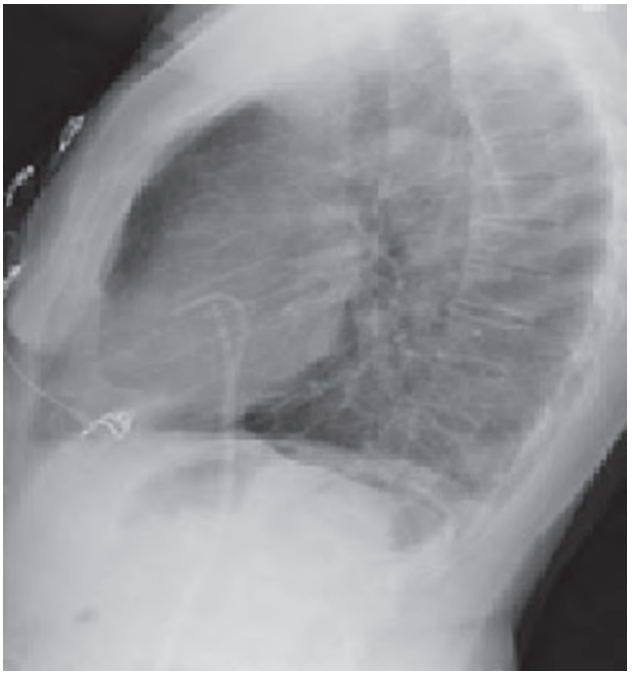
A Stormy Dialysis Catheter

Naeim G. Salah, Amit Kaushal. *University Health Network, Toronto, ON, Canada.*

Introduction: Central venous catheters (CVCs) are used to administer hemodialysis (HD) therapy. The CVC tip should be positioned in a central vein, with devices tips at the atriocaval junction (upper body CVC), and in the inferior vena cava (IVC, lower body CVC) [1]. Here we describe a case of life-threatening arrhythmia associated with CVC position.

Case Description: A 58-year-old female dialysis patient presented for cardiac testing for upcoming renal transplant. She was being dialyzed via a CVC due to failure of her arteriovenous fistula. Due to central venous stenosis, a 55cm tunneled right femoral CVC was placed in 2021. During her exercise stress echocardiogram, she developed ventricular arrhythmias 6.5 minutes into the test. The procedure was halted. She had 5 minutes of sustained ventricular tachycardia, with resolution of arrhythmias 8 minutes into recovery but was stable throughout. Coronary angiogram was negative. Chest x-ray demonstrated the CVC had a split-tip, both of which were in the right atrium. Cardiology determined the arrhythmia was related to irritation of the conduction system by a malpositioned CVC. The CVC was replaced with a new 31cm catheter resting in the IVC.

Discussion: Arrhythmias in HD patients are often attributed to ischemia, electrolyte abnormality, or systemic stresses [2]. Here, catheter position was considered the primary trigger. Though not documented, oscillation of the lumen tips during dialysis could also have precipitated intradialytic arrhythmia. While confirmation of CVC position by chest x-ray is standard for temporary upper body devices, it should be considered for any CVC where malposition could occur (e.g. small body size).



Lateral chest radiographs demonstrating deep position of CVC and split-tip catheter, respectively)

PUB161

Minimally Invasive Guidewire Exchange Technique for Tunneled Hemodialysis Catheters: Preservation of Venous Insertion Site in Chronic Hemodialysis Patients

Fernando A. Cuellar-Gonzalez,[1,2] Sebastian Consuegra-Flores,[1,2] Néstor H. Cruz Mendoza,[1] Mauricio Arvizu Hernández.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Tecnologico de Monterrey - Campus Ciudad de Mexico, Ciudad de Mexico, Mexico*.

Background: Tunneled hemodialysis catheter (THC) has become an acceptable form of vascular access (VA) when an arterio-venous fistula is not feasible or available. Dysfunction of THC is associated with removal and replacement of THC. Few techniques of guidewire exchange of THC have been reported. We aim to present the experience of our center in guidewire exchange of THC, with preservation of the same venous insertion site with only one incision at the jugular site, without fluoroscopy and local anesthesia performed by interventional nephrologist.

Methods: Retrospective, single-center study conducted between Jan/2018-May/2023. Guidewire exchange of THC due to dysfunction in 15 pts on chronic HD with preservation of venous insertion site and creation of a new subcutaneous tunnel with local anesthesia without fluoroscopy. Successful exchange, complications, and catheter patency were reported at 3 months.

Results: 15 procedures were performed in same number of patients, mean age 41.2 +/- 13.6 years, 53% were female, mean duration of HD was 3.2 years; 12 (80%) have one previous VA, all THC were located in right internal jugular vein. The success rate of the procedure was 100%. At 3 months, 12 cases remained functional, two catheters had not completed three months of follow-up, one catheter was removed earlier due to infection. Only mild complications, such as bleeding requiring sutures, were reported in two cases, with no major complications recorded.

Conclusions: Our study shows that the guidewire exchange of THC, with preservation of the same venous insertion site with only one incision at the jugular site is a reliable method in patients with dysfunction of THC and with low risk of complications.

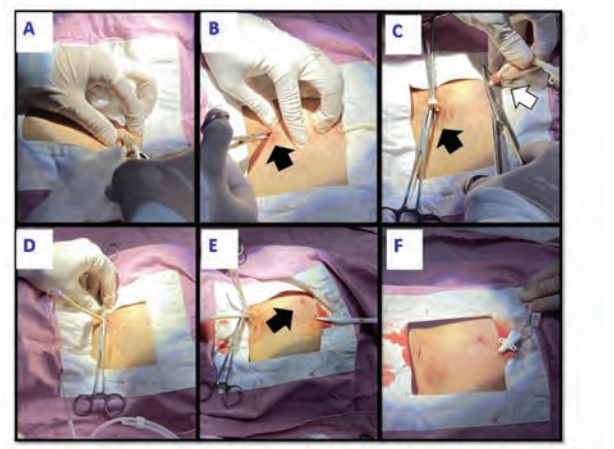


Figure 1. A) The cuff was released from the subcutaneous tissue, **with blunt disessection, without incision** B) An incision is made in the cervical region along the subcutaneous path of the catheter (arrow), and the tissue is dissected until the catheter is brought to the external surface. C) In the externalized portion, double clamping is performed proximal to the blood vessel (black arrow). A cut is then made in the region proximal to the clamping site (white arrow), and the distal portion of the catheter is removed. D) A guide is advanced through the distal end of the catheter to ensure venous access. E) A new tunnel is created laterally to the previous one (arrow).F) The procedure concludes with only one incision, which is sutured.

Patient's Navigator for Lupus Nephritis: Pilot Evaluation

Patricia Nogueira De Sa, Faith Ryu, Mia Kim, Himanshi Verma, Michael Go, Pranav S. Kancherla, Aylin Ergin, Laura Liu, Abdallah Sassine Geara. *University of Pennsylvania, Philadelphia, PA.*

Background: Systemic Lupus Erythematosus(SLE) is an autoimmune condition that disproportionately affects women, racial and ethnic minorities, and individuals of lower socioeconomic status[1]. Patients with SLE often face social determinants of health challenges that are barriers to care and influence health outcomes[2]. To improve outcomes, we implemented a patient's navigator program focused on addressing the medical and social needs of patients with lupus nephritis (LN).

Methods: In this pilot phase, we included 13 patients with LN that were identified by their treating physician with high medical needs (newly diagnosed or flare of LN;recent hospitalization or emergency room visit;or transitioning from pediatric to adult care) and/or high social needs (food and economic insecurity, uninsured; complex family situation with childcare or elderly care needs, high no-show rate, limited health literacy, mental health challenges). Initial screening was performed by college volunteers connected to the medical team who reviewed the results and implemented interventions aiming patient's specific needs. Follow-up assessments were arranged to modify the social determinants of health that negatively affected patients.

Results: The demographic and screening results are summarized in Table 1. Financial help with medication and physician visit copays were reported as the most pressing need followed by transportation, disease education and assistance with medication compliance. Based on the initial screening, we started an intervention plan tailored to individual needs such as financial support for transportation, social services, blood pressure machine, pill box and lupus education.

Conclusions: The pilot phase of our patient navigator program successfully identified additional medical and social needs for patients with LN. We plan to expand this program by identifying more patients and arranging for follow-up assessments to modify social determinants of health that negatively affect our patients. Our program can serve as a model for other institutions to improve outcomes for patients with SLE.

An International Public-Private Partnership Model for Renal Replacement Therapy in Uzbekistan: Lessons and Challenges

Suresh Sankarasubbaiyan, Botir Daminov, Savitha Kasiviswanathan, Dilshod Sobirov, Ravshanbek Raximov, Khurshid U. Dosimbergenovich, Shiva Chaudhary, Kamal D. Shah. *Nephrocare Health Services Pvt Ltd, Hyderabad, India*.

Background: Uzbekistan is part of New Independent States region in Europe with 35.6 million population and GDP/capita of 2254.9 dollars with an acute need for RRT availability and accessibility.

Methods: The Uzbekistan government chose a dialysis provider from India to initiate a public-private partnership model of RRT. Our objectives are 1. Describe the model for hemodialysis by roles, resources and service provided 2. Present demography, dialysis practice and clinical outcome from April-December 2022.

Results: Under the model, the government funded and governed while the private provider ensured leadership, human resources, technology, HD delivery and information capture (paper based & digital). HD facilites were at: Bogot (pop:10600), Nukus (pop:330,000) and Urgench (105,000) with machine capacity of 25, 34, and 31 respectively at 65% utlization (Image 1). B Braun dialog machines and Wego F18 Polysulfone 1.8m2 dialyzers were used. Staff patient raio of 1:3 with oversight by physicians with nephrology training. Image 2 presents patient, practice and outcome characteristics. Proximal public health facilites provided support for acute care and biochemical monitoring.

Conclusions: We demonstrate an emerging model of knowledge and skill transfer between LMIC in RRT with profound delivery challenges in acces to care, manpower and HD delivery in Uzbekistan.

Language Barrier and Abdominal Compartment Syndrome with Renal Replacement Therapy (RRT) in the Intensive Care Unit (ICU)

Alvin G. Kwon, Melissa Baker, Hanny Sawaf. *Cleveland Clinic, Cleveland, OH.*

Introduction: In the US, using a primary language other than English is a known barrier to adequate healthcare utilization and patients' comprehension of diagnosis and treatment. Adverse events were more prominent in limited English-proficient patients at 46.8% compared to 24.4% in English-proficient patients. Abdominal compartment syndrome (ACS) is commonly diagnosed with intra-abdominal pressure over 20mmHg and related organ failure such as AKI. However, ACS has nonspecific symptoms and poor physical exam sensitivity as low as 40-50% making it challenging for physicians to diagnose it promptly. We present patient with intra-bladder pressure proven ACS complicated by AKI required hemodialysis.

Case Description: Patient is a 25-year-old Spanish-only speaking male diagnosed with necrotizing pancreatitis after being found with septic shock requiring two vasopressors for blood pressure support. Patient was also found to have generalized weakness, abdominal distension, hyponatremia, and jaundice. The patient tested positive

for Confusion Assessment Method and needed to rely on a landline interpreter service. He had no family or social support to assist with his history. After rigorous intravenous fluid resuscitation for pancreatitis, patient remained anuric with lower extremities edema and was initiated on continuous veno-venous hemodialysis. Given his severe abdominal distention and tenderness on physical examination, intra-bladder pressure was measured at 29 mmHg while patient was still systemically hypotensive. Surgical intervention was not performed, given comorbidities and concerns that it caused more harm than benefit. Decompression via nasogastric tube and scheduled enema were continued and bladder pressure was decreased at 5 mmHg three days later. Unfortunately remained dialysis-dependent and passed away from worsening septic shock.

Discussion: Poor socioeconomic status and language barriers and confusion from encephalopathy are previously unrevealed risk factors for ACS that may contribute to mortality in vulnerable populations; additional barriers to communication with providers may make reporting symptom changes difficult. Therefore, physicians should pay extra attention to vulnerable people. Future studies between language barriers, socioeconomic status, and ACS should be followed.

PUB165

What Does Justice Require of Us in Kidney Health?

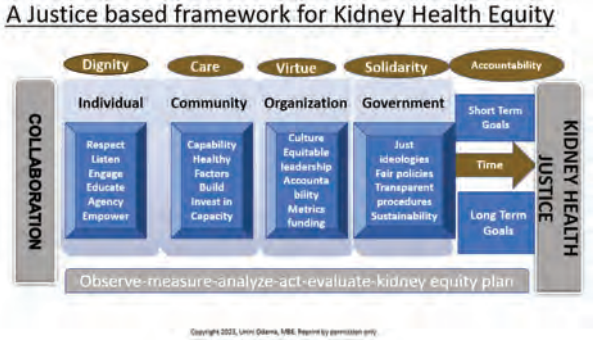
Unini Odama. *Harvard University, Cambridge, MA.*

Background: Thirty-seven million Americans live with chronic kidney disease, while over 800 000 have end-stage kidney disease (ESKD), a devastating life-altering condition. Unfortunately, kidney health disparities and inequities abound, and the current literature does not integrate a comprehensive view of justice in kidney health. Justice, the fair distribution of fundamental rights, duties, socio-economic, health, and healthcare opportunities, is linked to wellbeing. The overarching goal of this project was to demonstrate how kidney health, health equity, and justice are inextricably linked.

Methods: This work used a wide justice lens to explore the moral question of variances in kidney health metrics (disparities) and outcomes (inequities). Relevant peer-reviewed scientific journals and seminal justice articles were reviewed. Information was gleaned from discussion with Justice experts. Justice principles and relevant bioethical principles were linked to create a Kidney health justice-based framework.

Results: Findings unveiled widespread inequities in kidney disease risk, care, and outcomes. Common kidney disease risk factors- diabetes and hypertension- are 12-13 times more prevalent in Blacks; ESKD prevalence in Blacks (29.8 %) is quadruple that of Whites. Blacks and Hispanics are 53% and 65%, and 79% and 53%, less likely to receive home dialysis and kidney transplantation than Whites. Also, racism, poverty, and oppression are unique determinants of kidney health inequities.

Conclusions: This project illustrated the link between kidney health and justice with a novel justice-based kidney health framework, connecting normative justice theories to bioethical principles of dignity, care, virtue, and solidarity. An infographic highlighted the necessity for collaboration at the individual, community, organizational, and governmental socio-ecological levels. Justice requires policymakers and kidney care stakeholders to adopt a far-reaching, transparent, accountable, sustainable, and just kidney health plan.



PUB166

Use of Cell/Smartphone Technology in an Urban Free-Standing Hemodialysis Facility in the United States: A Single Center Study

Sujith K. Palleti,[1] Kavitha Vellanki,[1] Judith Beto,[2] Vinod K. Bansal.[1] *[1]Loyola University Medical Center Department of Nephrology, Maywood, IL; [2]Loyola University Health System, Maywood, IL.*

Background: Cell/smartphone has become a basic necessary commodity in the 21st century and a cornerstone for knowledge sharing. It can be a valuable resource for patient education when used appropriately. Data on cell/smartphone technology usage in the hemodialysis (HD) population is non-existent. We proposed to study the utilization of cell/smartphone technology in selected activities to better understand our patient population and identify the best means of communication.

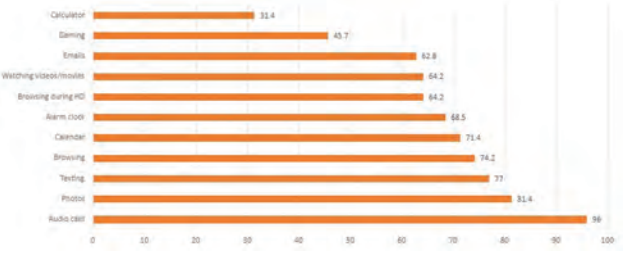
Methods: All patients receiving in-center dialysis were approached to complete a 2-page paper survey. Data collected included age, sex, self-reported ethnicity, presence of landline/internet at home, and ability to drive. The food security risk score was assessed using the USDA validated 2-question format.

Results: Of the 110 HD patients, 77 agreed to participate (70% response rate), and 70 of the 77 had a cell/smartphone. The baseline demographics of the study population are shown in Table 1. Image 1 demonstrates the various activities smartphone is used in our HD cohort. Interestingly, women used text messaging more frequently than men (82% vs. 68%), and those who used text messaging were found to be younger than those who did not (58.1 and 71.2; age in years). 64% reported active browsing on their phones while receiving HD. We did not find any association between the ability to drive and the food security risk score.

Conclusions: The use of social media platforms accessed by cell/smartphone technology should be explored to find better means of education and communication in HD patients.

Demographics of study population

Gender, N (%)	Male: Female 37 (52.9%): 33 (47%)
Mean Age, Years (SD)	61.7 (SD - 13.4)
Self-reported Ethnicity (N=70)	African American – 50% Hispanic, not white – 34% Caucasian, white – 13% Asian – 3%
Landline at home (%)	28.6%
Internet at home (%)	74.3%
Drove car in last 30 days	57.1%
Food security risk score (N=67)	High risk score – 6.8% Moderate risk score – 27.9% Low risk score – 70.6%
Dialysis access, N (%)	AVF - 39 (55.7%) AVG - 13 (18.5%) PC – 18 (25.7%)



Utilization of smart phone for various activities in our dialysis cohort

Assessing the Current Evidence on Environmental Sustainability in Nephrology: Protocol for a Scoping Review by the International Society of Nephrology, Emerging Leaders Program Cohort 2022-2024

Isabelle Ethier,[1,2] Divya P. Bajpai,[4] Brendan Smyth,[5,6] Winston W. Fung,[7] Maria Pippias,[9,10] Peace Bagasha,[14,15] Letizia De Chiara,[13] Ehab Hafiz,[11] Dearbhla M. Kelly,[3] Ugochi C. Onu,[12] Shaifali Sandal,[8] Workagegnehu H. Bilchut.[16] International Society of Nephrology – Emerging Leaders Program Cohort 2022-2024. *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]Mater Misericordiae University Hospital, Dublin, Ireland; [4]King Edward Memorial Hospital and Seth Gordhandas Sunderdas Medical College, Mumbai, India; [5]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [6]St George Hospital, Kogarah, NSW, Australia; [7]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [8]McGill University Health Centre, Montreal, QC, Canada; [9]University of Bristol Faculty of Health Sciences, Bristol, United Kingdom; [10]Southmead Hospital, Bristol, United Kingdom; [11]Theodor Bilharz Research Institute, Giza, Egypt; [12]University of Nigeria, Nsukka, Nigeria; [13]Universita degli Studi di Firenze, Firenze, Italy; [14]Mulago National Referral Hospital, Kampala, Uganda; [15]Makerere University, Kampala, Uganda; [16]University of Gondar, Gondar, Ethiopia.*

Background: Human-induced climate change is a significant threat to global public health. The healthcare sector contributes significantly to environmental damage through resource depletion and greenhouse gas emissions. Furthermore, nephrology practices have a disproportionately higher share in the carbon footprint produced by medical therapies (e.g. dialysis). This review aims to map the available evidence of green/sustainable nephrology in the literature to better understand the current lacunae in the evidence and challenges faced while adopting eco-friendly practices.

Methods: A search strategy, developed in collaboration with a medical librarian to be used in Medline, and adapted for other databases (PubMed, Embase, Cochrane Library, CINAHL), will be used to retrieve references. A secondary manual search of all references from included studies will be undertaken (snowballing approach). All publications (including original studies, case reports, editorials, review articles, editorial letters, positional statements from professional societies, and conference abstracts) addressing any environmental impact of activity in kidney care; current knowledge or awareness of environmental impact of kidney care impact; any activity, strategy or effort focused on environmental sustainability of kidney care activity; or any barrier or challenge faced in adopting environmentally sustainable kidney care activity will be included. A data extraction table will be used to record the key components and information from the retrieved papers. Extracted data will be analyzed qualitatively using preidentified and newly identified themes.

Results: Results will be summarized using descriptive statistics and narrative summaries around the identified themes, to explore the environmental impact of kidney care and the application of sustainability approaches.

Conclusions: Results from this scoping review, which should be available for presentation in the fall of 2023, will help facilitate the formulation of a planned toolkit by our group, based on relevant components identified, which can direct healthcare professionals to vital resources in sustainable nephrology.

PUB168

Renal School at Dubai Hospital: 15 Years of Predialysis Health Education Program

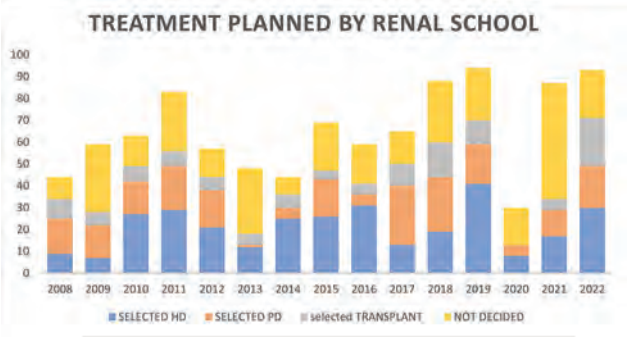
Hind H. Alnour, Fakhriya J. Alalawi. *DAHC, Dubai, United Arab Emirates*.

Background: For patients with end-stage renal disease (ESRD), renal replacement therapy (RRT) is necessary to sustain life. However, many pre-dialysis CKD patients lack the information to make wise healthcare decisions regarding their future management. We have a model program named Renal School, launched in 2008 and still working to date, and consists of a multispecialty team (including nephrologists, clinical dieticians, haemodialysis and PD nurses, psychologist, and social worker). We provide comprehensive education about various modalities of renal replacement therapy to patients with CKD stages 4 and 5 (eGFR<30 ml/min), aiming at reducing the need for emergency dialysis and catastrophic complications associated with delayed RRT.

Methods: Sine 2008 until date, 1021 patients attended renal school and were explained various modalities of RRT. Patients received a number of learning resources, and their preference for a particular modality was considered.

Results: Among 1021 patients, 315 selected haemodialyses, 217 opted for peritoneal dialysis, 119 were referred for pre-emptive kidney transplantation, and 332 remained undecided. Educated patients were prepared with access at the start of dialysis, which reduced complications associated with delayed dialysis therapy, had fewer hospital days of stay and had significant cost savings. Moreover, they received better care, enjoy better clinical outcomes, and cope better with the stresses of RRT. Although the majority (32.5%) could not decide regarding the type of RRT, yet they became more compliant with medication and dietary regimen, and they were able to plan healthy lifestyles and cope with their chronic illness.

Conclusions: By offering comprehensive information, fostering shared decision-making, providing psychosocial support, and addressing lifestyle management, these programs empower patients to actively participate in their healthcare decisions. Through their involvement, patients can select the most suitable RRT modality based on their preferences, leading to improved treatment outcomes and a higher quality of life.



PUB169

Reproductive Health Perceptions and Priorities of Males Living with CKD: A Survey Protocol

Nicole Larsen, Sofia B. Ahmed, Tessa A. Woodside, Victoria J. Riehl-Tonn, Shu Foong, Sandi M. Dumanski. *University of Calgary, Calgary, AB, Canada*.

Background: Chronic Kidney Disease (CKD) affects 1 in 10 Canadian males, and up to 80% of males living with CKD experience complications related to their reproductive health (sexual function and fertility). Despite its importance to overall health and quality of life, reproductive health is often overlooked during the management of CKD in males. This study aims to identify the reproductive health perceptions and priorities of males living with CKD.

Methods: An exploratory web-based survey will be designed through a comprehensive literature review and in consultation with experts in the field of nephrology, urology, and reproductive health. The survey will assess reproductive health perceptions and priorities of males living with CKD and will use both close- and open-ended questions. Survey pre-testing by patient partners will assess validity, usability, and functionality. Snowball sampling will be employed to recruit self-identified adult males living with CKD, with invitations disseminated through national and international CKD patient organizations, social media platforms, and CKD clinics in Calgary, Alberta, Canada.

Results: Descriptive statistics will be employed to analyze numeric and Likert-scale data, while conventional content analysis will be utilized to analyze open-ended data.

Conclusions: Reproductive health perceptions and priorities of males living with CKD are poorly understood. Our findings will guide future patient-directed research and encourage the development of targeted interventions to address the reproductive health needs of males living with CKD.

PUB170

Hemodialysis Dose as a Modifiable Sex-Specific Cardiovascular Risk Factor: A Systematic Review

Victoria J. Riehl-Tonn,[1] David D. Nicholl,[2] Sandi M. Dumanski,[1] Meghan J. Elliott,[1] Jennifer M. MacRae,[1] Colleen M. Norris,[3] Sofia B. Ahmed.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]The University of British Columbia, Vancouver, BC, Canada; [3]University of Alberta Faculty of Nursing, Edmonton, AB, Canada*.

Background: Cardiovascular (CV) mortality and morbidity may be reduced by increasing the hemodialysis (HD) dose above the current standard in females compared to males given sex-based differences in body composition and distribution of water. We sought to compare the associations between measures of HD dose and mortality (all-cause, CV-related) and CV morbidity between females and males receiving HD.

Methods: A systematic literature search of electronic databases (Medline, EMBASE, CENTRAL) was completed to identify articles including**:** 1) adult females and males on HD 2) measures of HD dose (Kt/V, urea reduction ratio, ultrafiltration rate) 3) all-cause and CV mortality and morbidity (coronary heart disease, myocardial infarction, ischemic or hemorrhagic stroke, venous thromboembolism, hypertension, heart failure, CV hospitalization) 4) original data (randomized controlled trial[RCT], quasi-RCT, cohort, case-control, cross-sectional study). All articles will undergo title and abstract screening before full-text review and data extraction and will be done independently by two investigators.

Results: Databases were systematically searched from inception to December 2022, which identified 24,051 articles eligible for title and abstract screening. Extracted data will include population characteristics, measures of HD dose, incidence of CV outcomes, study quality and risk of bias. Inter-reviewer reliability will be calculated at both phases. Data will be presented descriptively and meta-analysed using a random effects model. Heterogeneity will be explored and meta-regressed.

Conclusions: HD dose may be a modifiable sex-specific CV risk factor, with the potential to improve CV health in females on dialysis.

PUB171

Gender and Choice of Kidney Replacement Therapy: A Protocol

Victoria J. Riehl-Tonn,[1] Sandi M. Dumanski,[1] Meghan J. Elliott,[1] Jennifer M. MacRae,[1] Colleen M. Norris,[2] Sofia B. Ahmed.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta Faculty of Nursing, Edmonton, AB, Canada*.

Background: The prevalence of dialysis, a life-sustaining kidney replacement therapy(KRT), is rising annually at significant economic cost. Compared to in-center dialysis, home-based dialysis is associated with improved outcomes and lower cost yet may be underutilized. Currently, patient education addressing dialysis modality options is gender-blind. Therefore, the objective is to determine if measures of gender, including identity, roles and relations, are associated with KRT choice.

Methods: Exploratory mixed-methods study with online survey and semi-structured interview. Using a convenience sample, individuals with chronic kidney disease (Stage4-5) who have not yet initiated dialysis will be recruited from Kidney Care Clinics in Calgary, Canada. The exposure, gender and gender-related factors, will be measured using the Genesis-PRAXY Gender questionnaire, which encompasses gender identity, roles and relations. The outcome, participant's choice of KRT, will be measured through a survey and a semi-structured interview. Questions for survey and interview will be developed through a thorough literature review and in consultation with experts in the field.

Results: Data will be reported descriptively with proportions and percentages, when applicable. Non-parametric statistical tests, such as Kruskal-Wallis and Mann-Whitney U test, will be utilized to assess the association between gender-related factors and participants choice of KRT. Semi-structured interviews will be analyzed using a deductive thematic analysis where two independent reviewers will identify common themes.

Conclusions: Understanding the gender-related factors associated with dialysis modality choice will influence delivery of care in a gender transformative person-centred manner.

PUB172

Clinical Practice Gap Analysis of Anemia Associated with CKD

Amy Larkin, Linda Ritter. *Medscape Education, New York, NY*.

Background: Understanding clinical practice gaps in the clinical understanding of screening, health outcomes, and emerging treatments for anemia of chronic kidney disease (CKD) can inform development of tools to improve physician practices.

Methods: A survey instrument of 25 multiple choice, knowledge- and case-based questions allowed participants to assess their clinical knowledge with regard to anemia of CKD. The survey was available online to physicians without monetary compensation or charge. Respondent confidentiality was maintained and responses were de-identified and aggregated prior to analyses. Initial data collection occurred from August 12, 2022 to October 10, 2022.

Results: In total, 66 nephrologists completed the full assessment within the data collection period. Physicians demonstrated gaps in the following areas:

Conclusions: This educational research on assessment of physicians' clinical practices yielded important insights into clinical gaps related to anemia of CKD screening, health outcomes, and emerging treatments. Further studies are planned to assess the effect of medical education on decreasing these clinical practice gaps.

Funding: Commercial Support - Developed through independent educational grant from GSK

Topic	Incorrect Responses to Knowledge and Clinical Decision-Making Questions (%)
Main Cause of Anemia in CKD	33%
Regulation of Iron Absorption in CKD	30%
Strategies for Measuring Severity of Anemia in CKD	29%
KDIGO Guidelines for Anemia Screening in CKD	74%
Complications of Anemia of CKD	59%
Effect of Anemia on Patient Health Outcomes	42%
Health Inequities in Anemia of CKD	29%
Clinical Trial Data Related to Clinical Use of ESAs	47%

PUB173

Online Continuing Medical Education (CME) Improves Knowledge of Gaps in CKD-Anemia Management in Practice

Amy Larkin, Linda Ritter. *Medscape Education, New York, NY.*

Background: We sought to determine if online continuing medical education (CME) could improve the clinical knowledge and confidence of nephrologists and hematologists related to current gaps in care for patients with CKD-anemia.

Methods: The CME intervention comprised a 30-min online video-based roundtable discussion among 3 expert faculty with downloadable slides. The effects of education were assessed for learners completing both knowledge pre- and post-assessment questions using a matched pre-/post-assessment design, with participants serving as their own controls. A paired samples t-test was conducted for significance testing on overall average number of correct responses and for confidence rating, and a McNemar test was conducted at the question level (5% significance level, $P < .05$). Confidence was assessed in a 4th question using a 5-point Likert scale. The activity posted September 16, 2022, and data were collected through December 21, 2022.

Results: In total, 59 nephrologists and 35 hematologists answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation: Overall, 39% of nephrologists and 29% of hematologists improved their knowledge 27% of nephrologists and 14% of hematologists demonstrated improvements at recognizing disparities in the management of CKD-anemia (P<.01 for nephrologists, P=NS for hematologists) 22% of nephrologists and 20% of hematologists demonstrated improvements at recognizing the burden of disease of CKD-anemia (P<.05 for nephrologists, P=NS for hematologists) 27% of nephrologists and 43% of hematologists had a measurable improvement in confidence in overcoming gaps in management of CKD-anemia (P<.01 for both groups) Continued educational gaps: 39% nephrologists and 40% of hematologists need additional education related to disparities in the management of CKD-anemia 59% nephrologists and 40% of hematologists need additional education related to the burden of disease of CKD-anemia

Conclusions: This study demonstrates the success of online CME in a roundtable format on improving clinical knowledge and confidence of ER physicians and nephrologists related to managing patients with hyperkalemia. Continued knowledge gaps were identified for future educational targets.

Funding: Commercial Support - Developed through an independent educational grant from Glaxo Smith Kline

PUB174

Impact of Online Continuing Medical Education (CME) on Ability to Manage Patients with Dialysis-Dependent CKD-Associated Pruritus (DD-CKD-aP)

Amy Larkin, Donald Blatherwick. *Medscape Education, New York, NY.*

Background: We sought to determine if online continuing medical education (CME) could improve the clinical competence and confidence of nephrologists and primary care physicians (PCPs) related managing patients with dialysis dependent chronic kidney disease-associated pruritus (DD-CKD-aP).

Methods: Educational design included a "test, then teach" approach to elicit cognitive dissonance, with evidence-based feedback provided following each learner response. A repeated pairs pre-/post-assessment study design and a McNemar's test (P <.05 is considered significant) assessed educational effect, with Cohen's d being used to assess educational impact (<0.2 modest effect, 0.2-0.49 small effect, 0.5-0.79 moderate effect and >0.8 extensive effect). The activity launched November 4, 2022 and data were collected through January 24, 2023.

Results: In total, 108 nephrologists and 252 PCPs answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation: Overall, 85% of nephrologists and 81% of PCPs improved their competence (P<.01 for both groups). 55% of nephrologists and 52% of PCPs demonstrated improvements at screening for and diagnosing DD-CKD-aP (P<.01 for both groups). 42% of nephrologists and 63% of PCPs demonstrated improvements at managing DD-CKD-aP (P<.01 for both groups). 59% of nephrologists and 49% of PCPs demonstrated improvements at providing patient education related to DD-CKD-aP (P<.01 for both groups). 41% of nephrologists and 40% of PCPs had a measurable improvement in confidence in providing team-based management of CKD-aP (P<.01 for both groups). Continued educational gaps: 20% of nephrologists and 29% of PCPs need additional education related to screening and diagnosing DD-CKD-aP. 11% of nephrologists and 28% of PCPs need additional education related to managing DD-CKD-aP 8% of nephrologists and 30% of PCPs need additional education related to patient education for DD-CKD-aP.

Conclusions: This study demonstrates the success of online, text-based, interactive cases on improving clinical competence and confidence of nephrologists and PCPs related to managing patietns with DD-CKD-aP. Continued knowledge gaps were identified for future educational targets.

Funding: Commercial Support - Developed through an independent educational grant from CSL Vifor

PUB175

Online Patient Education Improves Understanding of CKD-Associated Pruritus

Amy Larkin, Donald Blatherwick. *Medscape Education, New York, NY.*

Background: This study assessed the impact of online patient education on knowledge, confidence and intent to act regarding chronic kidney disease-associated pruritus (CKD-aP).

Methods: The educational intervention consisted of 2 activities comprised of text, integrated visuals, and patient video commentary published on WebMD Education in 2022. Demographic questions were asked prior to each activity. Knowledge questions were asked both before and after to assess learning gains. Intent to change and confidence questions were asked at the end of each activity. Absolute improvements were calculated for pre/post questions.

Results: Activity 1: **Dialysis: Talking to Your Doctor About Your Skin** 9,355 learners; 327 completers of all questions 56% female; 53% white, non-Hispanic; 65% over 54 years of age After the education, 80 % intend to talk to HCP about CKD-aP; 81% confident in understanding changes that can happen to skin while on dialysis Activity 2: **Ways to Manage the Itch When You're On Dialysis** 938 learners; 213 completers of all questions 62% female; 64% white, non-Hispanic; 81% over 54 years of age 20% improvement in knowledge regarding ways to treat CKD-aP; 85% intend to talk to HCP about ways to help manage the itch while on dialysis; 80% confident in talking to HCPs about their skin and if itching happens [LA1]Data missing from dashboard, waiting on data

Conclusions: The metrics and outcomes gathered in this assessment are a strong indicator that online patient activities on WebMD Education improved knowledge and confidence and prompted intent to act related to CKD-aP.

Funding: Commercial Support - This education was supported by an independent educational grant from CSL Vifor.

Virtual Nephron: A Qualitative Assessment of a Virtual Reality (VR) Educational Tool

Georges Nakhoul,[1] Jonathan J. Taliercio,[1] Elias Bassil,[1] Susana Arrigain,[2] Jesse D. Schold,[2] John F. O'Toole,[1] S. Beth Bierer,[1] Joseph V. Nally,[1] John R. Sedor,[1] Ali Mehdi.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: The proliferation of VR technology has led to the creation of innovative educational tools. Using funding from the ASN, we developed a 3D VR renal physiology course. We present a qualitative analysis of its perceived utility.

Methods: Internal medicine PGY1 residents were randomly assigned into 2 groups: a VR group (exposed to the VR session) and a conventional group (received a printed script of the VR learning course). The VR session consisted of a 3D review of water and electrolyte transport and on diuretic mechanism of action. Within a week of the intervention, both groups underwent a 2-hour seminar on physiology of solute/water transport and diuretics. The VR group was asked to rate their VR experience at the end of the seminar. This was performed using a RedCAP-based survey consisting of a 4-point Likert scale. Residents randomized to the VR group were also asked to participate in a focus group. Sessions were recorded and transcribed verbatim. Data was analyzed through the content analysis approach by two independent reviewers who met to compare coding and reach consensus on emerging themes.

Results: Of the 64 PGY1 residents who were randomized to VR group, sixty-two completed the platform assessment. Overall, > 90% of the residents rated the platform positively in all parameters, and 77% preferred it as a teaching method (Table 1A). Three focus groups met for one hour. Each group respectively comprised 9, 8, and 15 interns from each academic years 2020-2023. Several recurring themes emerged in our analysis (Table 1B).

Conclusions: The feedback of the VR course was overwhelmingly positive and was perceived to be a helpful educational adjunct. Educational institutions should consider supporting the development of interactive educational tools to enhance leaner experience.

I was absorbed in the activity of the simulation	0	61(98.4)
The delivered material was clear	0	59(95.2)
The delivered material appropriately covered the learning objectives	1	59(96.7)
The Oculus Quest made it easy to understand the learning objectives	0	57(91.9)
The Oculus Quest is a useful learning aid	0	57(91.9)
Oculus Quest enhanced my understanding of nephrology concepts	0	58(93.5)
I found the Oculus Quest enjoyable to use while learning	0	60(96.8)
I preferred using the Oculus Quest to the conventional teaching method	0	48(77.4)
I would like the Oculus Quest to be utilized for more topics in nephrology	0	58(93.5)

Table 1A. Survey evaluating the VR platform

POSITIVE THEMES	NEGATIVE THEMES
Recall: memory anchor with recall that was described as relevant to clinical practice	Lack of immediate clinical relevance
Attention span: great hook	More interaction: somewhat passive experience despite interactive format
Interaction: engaging and powerful	Organization: VR and lesson to be taught concurrently
Spatiality: improves understanding of structures	Environment control: ability to change the speed of the simulation
Enjoyable: cool / fun / graphically appealing	Logistical challenges: inability to take notes
Great supplemental resource	Technical challenges: motion sickness, lag, teleportation feature

Table 1B. Focus group themes

Assessing ChatGPT's Reliability as a Novel Educational Resource for Interventional Nephrology

M. Salman Sheikh, Fawad Qureshi, Charat Thongprayoon, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Interventional Nephrology is a new subspeciality of Nephrology that focuses on ultrasound guided renal biopsy, insertion of peritoneal and tunneled dialysis catheters, and endovascular procedures for managing arteriovenous fistulas in dialysis patients. Additional educational resources are necessary to support its growth as a developing field. ChatGPT is an state-of-the-art language model with exceptional proficiency in natural language processing tasks, raising questions about its potential as an educational resource for interventional nephrology. However, its performance in this field has not yet been evaluated.

Methods: The Nephrology Self-Assessment Program (NephSAP) of the American Society of Nephrology (ASN) was utilized to evaluate the accuracy of ChatGPT in answering questions related to Interventional Nephrology. There was a total of 55 questions on NephSAP related to Interventional Nephrology. The question bank was executed twice using ChatGPT, and the level of concordance between the initial and subsequent runs was determined. Questions containing images were excluded from the assessment due to current limitations in ChatGPT's image processing capabilities.

Results: ChatGPT achieved an accuracy of 52% on the initial run and 60% on the subsequent run. The overall concordance between the initial and subsequent runs was 73%, with the same responses on 40 questions (73%) and different responses on 15 questions (27%). Correct concordance was 63%, while incorrect concordance was 38%. Among the 15 questions with different responses, ChatGPT revised 7 incorrect responses to correct responses on the subsequent run. Conversely, it also switched 5 correct responses to incorrect responses on the subsequent run. There were 3 questions on which ChatGPT's responses remained incorrect on both runs.

Conclusions: ChatGPT's accuracy in answering questions related to Interventional Nephrology was suboptimal with an overall accuracy of 56%. The concordance between the initial and subsequent runs also suggested that ChatGPT may be unreliable. Based on these findings, the current version of ChatGPT is not a dependable educational resource for nephrologists, nephrology professionals, or medical staff in this subspecialty. Further development would be necessary to enhance ChatGPT's performance in the field of Interventional Nephrology.

PUB178

Enhancing Patient Education Through Artificial Intelligence (AI): Evaluating ChatGPT's Accuracy in Providing Information on Living Kidney Donation

Oscar A. Garcia Valencia,[1] Iasmina Craici,[1] Caroline Jadlowiec,[2] Shennen Mao,[3] Michael A. Mao,[3] Napat Leeaphorn,[3] Pooja Budhiraja,[2] Charat Thongprayoon,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Arizona, Scottsdale, AZ; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Living kidney donation is a complex process and individuals seeking reliable information often turn to Frequently Asked Questions (FAQs) websites, such as Donate Life America. ChatGPT is an AI language model with the potential to offer accurate information on various topics including living kidney donation. However, its effectiveness in addressing patient queries specific to this topic has not been assessed. We aimed to evaluate ChatGPT's performance in providing accurate information on living kidney donation by comparing its answers with those provided by nephrologists and a widely accessible FAQs website.

Methods: The study collected 27 questions on living kidney donation from the Donate Life America's website and divided into four steps: original questions, paraphrased questions with different interrogative adverbs, paraphrased questions with verbs and prepositions removed, and paraphrased questions with misspelled words. ChatGPT's answers to each question were compared with those provided by the FAQs website and nephrologists to evaluate its accuracy.

Results: ChatGPT's accuracy varied depending on the question type. ChatGPT provided correct answers for 85.2% of the original questions. Notably, when the questions were paraphrased with different interrogative adverbs or with verbs and prepositions removed, correct answers were provided by ChatGPT in 96.3% and 92.6% of the cases, respectively. The accuracy decreased to 85.2% when the questions contained misspelled words. The original questions were tested a 2nd time with an accuracy of 92.6%. The overall concordance in correct answers between the 1st and 2nd test of the original questions was 85.2%.

Conclusions: This study highlights ChatGPT's promising accuracy, in providing reliable information on living kidney donation. ChatGPT consistently demonstrated accuracy rates of >85% across a range of question formulations, including original questions and paraphrased versions. However, caution should be exercised when relying on ChatGPT's responses to questions with misspelled words. The study suggests that further advancements are needed to enhance ChatGPT's performance and ultimately improve patient education.

PUB179

Nephrology Program Director Protected Time for Training Program Administration: A Follow-Up Survey

Christina M. Yuan,[1] Brian Y. Young,[2] Maura A. Watson,[1] Amy N. Sussman.[3] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]University of California Davis School of Medicine, Sacramento, CA; [3]The University of Arizona Health Sciences, Tucson, AZ.*

Background: In 2022-23, the Accreditation Council for Graduate Medical Education (ACGME) reduced minimum required program director (PD) protected time from 0.25 (10 hrs/week) to 0.2 FTE (8 hrs/week) for programs with <7 approved fellow positions. A survey of nephrology PDs in April 2022 found that 48% were not receiving the minimum 10 hrs/week.

Methods: A 22-question, anonymous follow-up survey was sent to all US adult nephrology PDs (March 2023) on how much protected time they received in 2022-23 and how much they needed to effectively administer their programs. We compared results with 2021-22, asked how PDs would use extra time if provided and assessed PD potential for burnout."

Results: Response was 62% (92/149) with 88% completion. Geographic distribution and number of approved positions was similar to the national profile. 61% had <7 approved fellow positions. Median protected time for 2022-23 was 10 hrs/week [IQR 6.25,12]; 8 hrs/week [IQR 4,10] for programs with <7 fellows. 40% of programs were not in compliance with protected time requirements, regardless of approved fellow number. 37% (30/81) of PDs agreed they had "enough protected time to effectively administer my program." PDs at smaller programs (≤ 4 and 5-6 fellows) estimated needing a minimum 10 hrs/week for effective program administration (16 hrs/week for >10 fellow programs). The top 3 tasks PDs would focus on if they had more time were 1) improve didactic curriculum (60%); 2) develope individualized fellow learning pathways (48%); 3) mentor fellow scholarly work (46%). 51% indicated they would prefer defined protected time in hrs/week for each program leadership member. Only 15% would prefer a block of time divided between faculty as they saw fit. 22% (18/81) were at high risk for emotional exhaustion, reporting feeling "burned out from my work" daily or a few times a week.

Conclusions: PDs report needing more protected time to complete necessary administrative and didactic tasks--a minimum 10 hrs/week regardless of program size. This would allow PDs to focus on improving fellow didactics and developing individualized fellow learning pathways, as recommended by the 2022 ASN Taskforce on the Future of Nephrology. *The views expressed in this abstract are those of the author(s) and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

PUB180

Surveying the Nephrology Landscape: A Targeted Needs Assessment Among Resident Learners

Christina L. Tamargo,[1] John Sperati,[1] Christiana M. Zhang,[1] Paul D. O'Rourke,[1] Stephen M. Sozio.[1,2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Interest in a nephrology career has waned among residents. Knowledge gaps and lack of exposure may contribute to this. Survey-based needs assessments have identified educational needs among nephrology fellows, but research targeting internal medicine residents is limited.

Methods: We distributed an electronic survey to internal medicine and medicine-pediatrics residents at two academic teaching hospitals in Maryland in fall 2022. It included four sections: demographics, training, kidney disease topics, and educational resources. We analyzed responses using mixed methods including descriptive statistics, Spearman correlations, and inductive thematic analysis.

Results: Forty-nine of 208 residents completed the survey (24% completion rate). Those who had completed more time on nephrology rotations were more likely to have considered a nephrology career (P=0.006). The resources residents used most frequently and deemed most helpful are displayed in Figure 1. Residents felt most knowledgeable about hypertension (average 3.8 on a 5-point scale) and least knowledgeable

about transplant nephrology (1.5/5). They most desired additional instruction on tubulointerstitial disease (51%). Suggestions for improvement in nephrology education centered around increased exposure to nephrology faculty, additional clinical rotations in nephrology, more nephrology teaching, and greater availability of nephrology resources.

Conclusions: Residents are interested in learning about nephrology topics and having nephrology incorporated more consistently into the internal medicine residency curriculum. These findings will help guide the creation of educational interventions to increase residents' knowledge of and interest in nephrology.

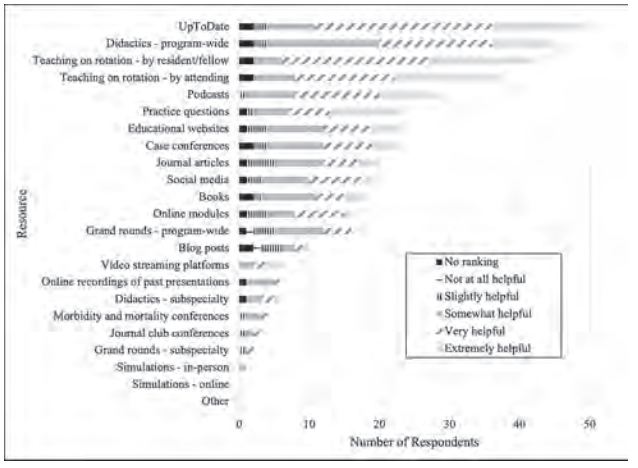

Figure 1. Value of educational resources reported by internal medicine residents.

PUB181

Does an Online Curriculum for Continuous Renal Replacement Therapy Affect Internal Medicine Trainee Knowledge?

Amol M. Patel,[1] Sarah F. Sanghavi.[1,2] *[1]University of Washington School of Medicine, Seattle, WA; [2]VA Puget Sound Health Care System Seattle Division, Seattle, WA.*

Background: Current online resources of continuous renal replacement therapy (CRRT) do not focus on its clinical application at the resident level. We developed an interactive, video-based online curriculum on CRRT with learning objectives specifically designed for internal medicine residents. We aimed to improve resident fluency with CRRT using a stand-alone educational resource.

Methods: We sent an online needs assessment survey to internal medicine residents at our institution. This was followed by voluntary study participation. Our study included two arms: The control arm completed a 10-question knowledge assessment. The intervention arm participated in an interactive 20-minute online curriculum module prior to completing the same knowledge assessment. Participants in the intervention arm also completed a post-curriculum survey.

Results: Our needs assessment showed that residents had minimal instruction on CRRT but were interested in learning. Baseline characteristics and results can be seen in Table 1. Participants in the intervention arm scored higher on the knowledge assessment than the control. There was no difference based on PGY level or prior nephrology rotation experience. All (100%) of those who completed the curriculum recommended the module to their peers and thought the length was appropriate. An important limitation was low participation rate: 188 participants were surveyed, and 36 (19%) responded.

Conclusions: This study demonstrates a stand-alone module can improve resident knowledge in CRRT. Participants in the intervention arm performed better on an assessment irrespective of PGY level and prior nephrology rotation experience. Further studies will aim to optimize trainee participation.

Results

	Performance
Control (28)	73 %
Intervention (8)	98 %
R1 (13)	84 %
R2 (12)	77 %
R3 (9)	73 %
R4 (2)	75 %
Completed Nephrology Rotation (15)	78 %
Did Not Complete Nephrology Rotation (21)	79 %
Future Career Plan is Nephrology (4)	95 %
Future Career Plan is Not Nephrology (32)	76 %

PUB182

Improving Dialysis Nursing Burnout with Innovative Technology Training

Mary A. Luckett,[1] Christie D. Holmes,[2] Cynthia J. D'Alessandri-Silva.[2] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Outset Medical, San Jose, CA.*

Background: Nursing burnout is prevalent due to both rising shortages and increased workload. Studies cite dialysis nurses lack time and resources necessary for patient care. Furthermore, nurses in public hospitals are at higher risk for compassion fatigue, creating a greater need for change. Many owe the burnout to frequent complex patient interactions, high levels of depersonalization in poor work environments and complex technology. With respect to technology, a newer dialysis device, cleared in 2018 produces dialysate on demand for use in the acute, chronic, and home settings. The Tablo system offers a coordinator training program to ease implementation of this innovative technology. This reports findings from the training program.

Methods: An electronic survey was distributed to trainees enrolled in the Tablo coordinator program from May 2020-April 2023 (n=439). Questions included demographic hospital setting, dialysis experience, comfort with troubleshooting alarms and net promoter scores.

Results: Results from 399 respondents (90.88% overall response rate), from 187 unique facilities were analyzed. Most were dialysis or critical care nurses (24.56% and 25.81% respectively), worked in a hospital (82.20%) and greater than 5 years dialysis experience (53.38%). Many have never managed or managed less than 5 treatments on Tablo before training (58.16%), over 87% were extremely satisfied with the Tablo learning curve and 77.2% felt prepared for survey readiness. 88.97% of participants would highly recommend the Tablo Coordinator program to their friends and colleagues. 130 participants reported being either satisfied or very satisfied after training, see Table 1.

Conclusions: In summary, most nurses trained on this innovative technology feel they can perform tasks successfully and are looking forward to working with the device. This Tablo training program will help combat the stressors that dialysis nurses are faced with daily, leading to burnout. More research is needed to address the burnout issue in the dialysis sector.

Funding: Commercial Support - Outset Medical

Results of survey after training program

	Can perform most tasks successfully	Can perform some tasks	Not comfortable performing most tasks
Training and coaching new nurses†	124 (95%)	5 (3.8%)	1 (0.7%)

PUB183

Impact of the Preclinical Renal Block on Medical Students' Attitudes Toward Nephrology

Anameeka Singh, Yara Abumohsen, Koyal Jain. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Teaching during the medical students' (MS) clinical years is critical in deciding what specialty they pursue. Previous research in nephrology and other fields (e.g. psychiatry, general surgery) has explored the impact of clinical rotations on a medical student's attitudes and preference for that specialty as a future career. Per our literature review, this is the first study to evaluate the impact of education in the pre-clinical years on a medical student's preference towards nephrology. We present the impact of the Renal Block (4-week pre-clinical nephrology curriculum for first-year MS) on students' attitudes towards nephrology and their desires to pursue nephrology as a specialty.

Methods: We administered a survey to first-year MS at the University of North Carolina School of Medicine (Chapel Hill, NC) for the 2022-2023 academic year [n=194]. This survey was distributed before and after the Renal Block and consisted of attitude-based questions that aimed to evaluate students' perceptions and preferences.

Results: Pre-survey response rate was 51.5% (100/194) and post-survey response rate was 40.2% (78/194). Not all questions were answered by every student. 92% of the students found the field interesting after Renal Block as compared to 76% before the block. 90% felt that the block increased their interest in nephrology. Work-Life Balance, intellectual curiosity and long-term patient relationships were the top 3 factors affecting choice of specialty amongst MS (Table 1).

Conclusions: The three key findings were: 1) More students became interested in nephrology as a subject and/or career choice post-Renal Block; 2) Work-life harmony is an extremely important factor to students when choosing a specialty to pursue; and 3) Per students' responses on short answer, the individual teaching the Renal Block had a major impact on student experience. Thus, pre-clinical nephrology teaching has a huge impact on MS attitudes towards nephrology.

Table 1: Comparison of pre- and post-surveys including factors affecting specialty choice

	Pre-Survey		Post-Survey	
Survey Statement	Disagree	Agree (includes unsure)	Disagree	Agree (includes unsure)
"I find the field of nephrology interesting."	24.32% (18/74)	**75.68%** (56/74)	7.94% (5/63)	**92.06%** (58/63)
"I could see myself as a nephrologist in the future."	59.46% (44/74)	**40.54%** (30/74)	44.26% (27/61)	**55.74%** (34/61)
"The Renal Block increased my interest in nephrology."			10.29% (7/68)	**89.71%** (61/68)
"The Renal Block changed my perspective on nephrology."			1.49% (1/67)	**98.51%** (66/67)
Factors Affecting Choice of Specialty	**Number of times listed amongst top 3 factors (Pre-Survey)**		**Number of times listed amongst top 3 factors (Post-Survey)**	
Work-Life Balance	**81.33%** (61/75)		**85.71%** (54/63)	
Intellectual Curiosity	**54.67%** (41/75)		**60.32%** (38/63)	
Long-Term Relationship w/ Patients	**46.67%** (35/75)		**47.62%** (30/63)	

PUB184

Creation of a Comprehensive List of Interventional Nephrology Training Centers in the United States

Aisha Shaikh,[1,2] Vandana D. Niyyar,[3] Sayee Sundar Alagusundaramoorthy.[4]
[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY; [3]Emory University, Atlanta, GA; [4]University of Kentucky, Lexington, KY.

Background: Interventional Nephrology practice in the United States (US) began in the private sector in the 1990s. Unlike other nephrology sub-specialties, the training of Interventional Nephrology in the US is available in both academic and private practice centers. There needs to be a comprehensive resource that outlines the details of the Interventional Nephrology training programs in the US. This lack of resource has created a barrier for nephrology trainees interested in pursuing Interventional Nephrology training. The Training and Workforce Committee of the American Society of Diagnostic and Interventional Nephrology (ASDIN) aimed to develop a comprehensive list of Interventional Nephrology training programs in the US.

Methods: The Training and Workforce Committee of the ASDIN sent an electronic survey to all ASDIN members. The survey questionnaire focused on the type of Interventional Nephrology training center (academic/hospital-based or private practice), type of Interventional Nephrology procedure training, duration of training, and eligibility for Interventional Nephrology training for trainees on Visitors International Stay Admission (VISA).

Results: We received survey responses from the Medical Directors of 27 Interventional Nephrology training centers. Of these 27 centers, 14 were academic or hospital-based, and 13 were private practice centers. 17 of these centers were accredited by ASDIN. All centers provide hemodialysis vascular access procedure training, 10 centers provide peritoneal dialysis catheter placement training, and 13 centers provide endovascular arteriovenous fistula creation training. The duration of Interventional Nephrology training varied across the centers, and in majority of the centers, the training duration was either 3-6 months (9 centers) or 6-12 months (9 centers). Eligibility for Interventional Nephrology training based on the trainees' VISA status was variable, with 5 centers offering training to J-1 VISA holders.

Conclusions: To date, this is the most comprehensive list of the Interventional Nephrology training programs in the US. The list is available on the ASDIN website: https://www.asdin.org/page/trainingcenters. This list will be an invaluable resource for nephrology trainees interested in pursuing Interventional Nephrology training.

PUB185

Increasing Attitudes Toward the Field of Nephrology Using Interactive Dialysis Modules for Trainees

Rahul Maheshwari. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: End-stage kidney disease and dialysis-dependent patients form a significant portion of the hospital population encountered by resident physicians. However, these trainees often lack formal education and confidence in managing dialysis-related care. Previous studies have indicated that trainees find kidney disease complex, contributing to decreased interest in nephrology. Additionally, there is a need for interactive educational tools to facilitate learning. This study aimed to assess the impact of interactive online modules on dialysis knowledge acquisition and attitudes towards nephrology.

Methods: We created five case-based interactive online modules, each focusing on an indication for acute dialysis initiation (acidosis, electrolyte abnormality, intoxication, volume overload, uremia) and linking these to fundamental dialysis principles (diffusion, convention, ultrafiltration, adsorption). The modules were designed to be completed within 10-20 minutes. Learner responses guided the progression of cases, providing detailed explanations for incorrect responses and concise synopses for correct responses. Modules were distributed among internal medicine resident physicians and medical students for voluntary completion. Pre- and post-module assessments included a 5-point knowledge questionnaire and a 4-point Likert scale survey measuring attitudes towards nephrology concepts and careers.

Results: 27 participants responded (16 pre-curriculum, 11 post-curriculum), including one medical student. Post-curriculum knowledge assessment scores showed improvement compared to pre-curriculum scores (3.3 vs. 4.5, $p < 0.01$), driven primarily by PGY-1 responses (2.9 vs. 4.5, $p < 0.01$). While attitudes towards the field of nephrology did not improve significantly, there was a decrease in participants who found dialysis intimidating (3.2 vs. 2.7, $p = 0.03$).

Conclusions: The study demonstrated that interactive online modules enhanced participants' knowledge of dialysis concepts and increased their comfort in managing dialysis patients, particularly among internal medicine trainees. Although attitudes towards nephrology careers were unchanged, this would not be expected from a single intervention. These modules could be combined with other strategies to improve nephrology knowledge and generate greater interest in the field.

PUB186

A Successful Resuscitation: Bedside Native Kidney Biopsies Performed by Nephrology Fellows at an Academic Tertiary Care Center

Eily Hayes, Blaithin A. McMahon, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

Background: Biopsy is the gold standard for diagnosing renal pathology, and performance of percutaneous kidney biopsy is a core curriculum requirement for ACGME graduate medical education in nephrology. The growth of interventional radiology and COVID-19 pandemic-related department restructuring and staffing turnover significantly decreased fellows' opportunity to perform and gain clinical competency in kidney biopsies at our academic tertiary care center. Faculty and fellows developed a new protocol for performing low-risk ultrasound guided biopsies at bedside, resulting in a significant increase in kidney biopsies performed by nephrology.

Methods: A protocol for low-risk kidney biopsies performed at bedside by nephrology was developed and implemented. The protocol included indications and contraindications for biopsy, characteristics of low-risk biopsy patients, pre-biopsy clinical management guidelines, the biopsy procedure, standardized post-biopsy orders, and templates for related documentation. The protocol was revised to address institution-specific challenges as they arose. Data regarding the number of biopsies, complications, and diagnoses were recorded and analyzed.

Results: From June of 2020 through December 2021, two bedside kidney biopsies were performed by nephrology fellows (1.26 biopsies per year). The new protocol was implemented at the start of the 2022-2023 academic year. In the subsequent 11-month period, ten biopsies were performed at bedside by nephrology fellows (10.91 per year), an 864-percent increase. One of the ten biopsies (10%) was complicated by subcapsular hematoma; though our sample size is small, this rate comparable to that in a systemic review and meta-analysis of over 118,000 renal biopsies as published in CJASN in 2020 (11%). Data collection is ongoing, but an additional benefit at our institution has been that patients can be biopsied, and diagnosis obtained, earlier in the clinical course.

Conclusions: At our tertiary academic center, a protocolized approach to low-risk kidney biopsies at bedside has significantly increased the number of kidney biopsies performed by nephrology. An unanticipated benefit is that low-risk patients have had shorter wait-times for biopsy, allowing for tissue diagnoses and initiation of treatment earlier in the clinical course.

PUB187

Observations from the POCUS Precourse at the NKF 2023 Spring Clinical Meetings

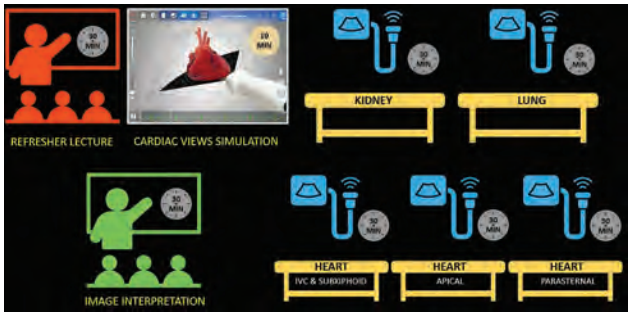
Abhilash Koratala,[1] Nathaniel C. Reisinger.[2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]University of Pennsylvania, Philadelphia, PA.*

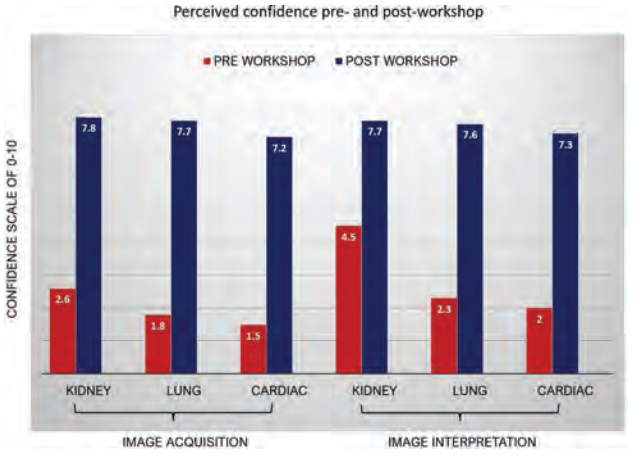
Background: In April 2023, a POCUS precourse was conducted at the National Kidney Foundation (NKF) Spring Clinical Meetings with the intent of providing foundational knowledge and practical skills necessary to perform basic scans pertinent to nephrology.

Methods: To maximize the time for hands-on learning, a set of 5 recorded lectures was provided to the registrants as pre-reading material. The workshop structure consisted of two identical 4-hour sessions (AM & PM) accommodating 16 and 23 learners respectively. See Figure 1 for the layout. An anonymous post-course survey was sent out, answered by 25 unique respondents (response rate 64.1%).

Results: The respondents were asked to rate their perceived confidence in acquiring and interpreting POCUS images on a scale of 0-10. The confidence in acquiring kidney images increased significantly from 2.6 ± 2.3 (mean ± SD) before to 7.8 ± 1.5 after the workshop ($p<0.001$). Confidence in acquiring lung and cardiac images showed a remarkable improvement (1.8 ± 2.4 to 7.7 ± 1.5 [$p<0.001$] and 1.5 ± 2.2 to 7.2 ± 1.3 [$p<0.001$] respectively). In addition, the respondents reported a substantial improvement in their confidence in interpreting kidney, lung, and cardiac ultrasound images (4.5 ± 2.2 to 7.7 ± 1.1 [$p<0.001$], 2.3 ± 2.4 to 7.6 ± 1.5 [$p<0.001$] and 2 ± 2 to 7.3 ± 1.5 [$p<0.001$] respectively) [Figure 2].

Conclusions: The NKF POCUS precourse was successful in improving confidence of the participants in acquiring and interpreting basic scans. While confidence does not necessarily imply competence, it serves as a motivating factor for continued practice. It is not realistic to expect improvement in competence via a half-day workshop.





PUB188

Nomophobia: Phone-Lessness Phobia Among Kidney Professionals

Aakanksha Singh,[1,2] Sawsan Tawfeeq,[2] Priyal D. Mehta,[2] Ripudaman S. Munjal,[3] Pranjal Sharma,[4] Tanja Kovacevic,[5] Diksha Mahendru,[2] Varun Monga,[6] Venkata S. Buddhavarapu,[7] Abhishek Kashyap,[8] Zara Arshad,[9] Faisal A. Nawaz,[10] Rahul Kashyap.[11] GRRSP - Global 3-P Study Investigators.
[1]MGM Institute of Health Sciences, Aurangabad, India; [2]Global Remote Research Scholars Program, St. Paul, MN; [3]San Joaquin County, Stockton, CA; [4]Northeast Ohio Medical University, Rootstown, OH; [5]Unversity Hospital of Split, Split, Croatia; [6]Banner Health, Phoenix, AZ; [7]Banner Baywood Medical Center, Mesa, AZ; [8]Sir Seewoosagur Ramgoolam Medical College, Vacoas-Phoenix, Mauritius; [9]Shifa College of Medicine, Islamabad, Pakistan; [10]Al Amal Psychiatric Hospital, Al Aweer, United Arab Emirates; [11]WellSpan Health, York, PA.

Background: The nature of healthcare providers' work demands continuous connectivity and accessibility to digital resources eg. quick access to medical references, patient information and teleconsultations. Nomophobia, also known as "No Mobile Phone Phobia", refers to anxiety, or nervousness caused by not being in contact with a mobile phone. There is paucity of literature to explore the prevalence and severity of nomophobia among kidney professionals.

Methods: A cross-sectional pilot study was conducted among healthcare professionals from April-May 2023. This abstract includes responses from attending physicians, fellows, nurses, advanced care providers (APP) and dialysis technicians. A web-based validated survey was shared using emails and social media applications such as whatsapp, linkedin and twitter. The study was IRB-exempt.

Results: A total of 100 responses were recorded from 10 countries in this ongoing survey. There were 49% females, with the highest representation in the age (in years) between 35-45(35%) and 25-35(25%). Approximately 50% of the respondents were Asians, 36% were White, 5% were Hispanics, and 2% were Black. The kidney professionals included attending physicians (38%), nurses (23%), fellows (11%), and APP (8%). The majority years of experience was of 6-10 (28%). Nearly 50% kidney professionals reported using their smartphones for more than 2 hours at work, and 64% reported using them for personal activities for up to 4 hours (Fig. 1). A vast majority (74%) was an I-phone user. The nomophobia prevalence of mild, moderate, and severe nomophobia were 13%, 52%, and 34%, respectively.

Conclusions: This pilot study denotes that the 2/3rd kidney professionals have self-reported nomophobia. Early recognition and management of nomophobia are crucial for improving work-life balance, and ensuring their wellbeing in the evolving digital era.

Provider Education to Improve AKI Outcomes and Awareness: A Scoping Review

Patricia F. Kao,[1] Emily C. Capellari,[2] Ashita J. Tolwani,[3] Daniel P. Murphy,[4] Linda Awdishu,[5] Marlies Ostermann,[6] Jorge Cerda,[7] Michael Heung.[2]
[1]Washington University in St Louis, St Louis, MO; [2]University of Michigan Medical School, Ann Arbor, MI; [3]The University of Alabama at Birmingham College of Arts and Sciences, Birmingham, AL; [4]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [5]University of California San Diego, La Jolla, CA; [6]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [7]Albany Medical College, Albany, NY.

Background: Acute kidney injury (AKI) care is often fragmented due to lack of healthcare team member knowledge regarding AKI. The goal of the AKINow Initiative Education Subcommittee is to increase AKI awareness and establish best practices in AKI education to optimize outcomes. We sought to characterize the current state of provider-focused AKI education by reviewing available literature on this topic.

Methods: Ovid Medline and CINAHL searches identified literature on provider-focused AKI education and awareness. Search strategy included keywords and Medical Subject Headings related to AKI, education, information, specific educational materials, and purpose for information sharing. To increase sensitivity, adjacency searching was used in lieu of phrases for the provider education and information concepts. No limits were applied to the results. After screening for relevance based on inclusion criteria of: 1) AKI population, 2) provider-focused education, the characteristics of included abstracts were summarized.

Results: Search criteria identified 187 abstracts; 140 were excluded (55 non-AKI focus, 78 without focus on provider education, 7 other); 47 abstracts met inclusion criteria, 37/47 (79%) were published prior to 2019. Journal types included 30/47 (64%) biomedical, 16/47 (34%) non-physician provider, and 1/47 (2%) bioinformatics. Target learners were providers involved in AKI prevention 11/47 (23%), AKI treatment 21/47 (45%), and care for AKI at multiple stages 15/47 (32%). Study designs included 9 cross-sectional survey studies of provider AKI awareness and knowledge, 23 review articles published as educational resources, 1 editorial, and 14 prospective, non-randomized studies of educational interventions reporting the following Kirkpatrick level outcomes: Level 1 (learner reaction), 1/14 (7%); Level 2a (change in attitude), 3/14 (21%); Level 2b (change in knowledge) 3/14 (21%); Level 3 (behavior change), 5/14 (36%); Level 4a (organizational change), 3/14 (21%); Level 4b (patient benefit), 5/14 (36%).

Conclusions: There is a paucity of literature, particularly since 2019, on the AKI education of providers. High-level evidence exploring educational interventions to close AKI knowledge gaps amongst healthcare team members are needed to improve transitions of care and clinical outcomes for patients with AKI.

PUB190

Metformin-Associated Lactic Acidosis

Chibueze E. Nnonyelu. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: Metformin increases plasma lactate levels in a plasma concentration-dependent manner by inhibiting mitochondrial respiration predominantly in the liver. The presence of an anion gap in a diabetic patient on Metformin, especially if associated with evidence of renal insufficiency should prompt clinicians to consider metformin as a contributing factor.

Case Description: Patient is a 49 F with a history of ICH 2/2 AVM, obstructive hydrocephalus with VP shunt, HfrEF (EF 15 to 20%), T2DM, HTN, who presented to the ER with AMS. Over the past few days, she had been feeling sick and had poor appetite, she, however, had been compliant with her medications which include, Metformin 1000mg BID, Lasix, spironolactone, and others. She had been on Metformin for 2 years. She was reported to have ventricular arrhythmia for which she got defibrillation and was given amiodarone. Her initial vital signs on arrival were BP 128/95, HR 123, RR 28, and SpO2 89% on room air. She was intubated in the ED due to respiratory distress and then transferred to the ICU. Physical exam showed dry oral mucosa, S1 S2 present, no added sound and lungs are clear, +2 pedal edema. Initial labs showed BUN 70, Cr 7.54, Na 138, K+ 8.1, Co2 4, Cl 95, Anion Gap 35, troponin 92 ng/l, Lactate 16.36, pH 6.85, WBC 19.2, no bands, CT head was negative, EKG sinus rhythm, wide QRS, no ST changes. Nephrology initiated emergent CVVHD. By day 2 in ICU, she was extubated, and on day 3, underwent a trial of Hemodialysis. She was discharged from the ICU on day 4.

Discussion: MALA is a rare but significant complication from metformin in the setting of renal insufficiency. A high index of suspicion is required to make the diagnosis. Lactic acidosis resulting from metformin toxicity should be suspected in any patient who has all of the following five criteria: a history of metformin administration, lactate level > 15, anion gap >20; pH 7.1or less, Co2 < 10, and a history of renal insufficiency GFR< 45 or cr > 2. It is well documented that acidosis leads to low contractility of the cardiac Myocytes. This coupled with HrEF in the patient led to Ventricular arrhythmia and cardiac arrest. Hemodialysis is the most preferred mode of therapy in hemodynamically

stable patients however CVVHD could be substituted in patients in shock. Education of both patients and providers to avoid metformin when there is a risk of renal failure, particularly with hypovolemia, is crucial to prevent MALA.

PUB191

Treatment of Severe Hyponatremia with Urea in Liver Cirrhosis

Mahendra L. Agraharkar,[1,2] Abinay S. Vanteru,[3] Krishna Vani Nemalidinne.[4] Space City Associates of Nephrology. *[1]The University of Texas Medical Branch at Galveston, Galveston, TX; [2]Baylor College of Medicine, Houston, TX; [3]BLK Max Superspecialty Hospital, New Delhi, India; [4]BLK Max Hospital, New Delhi, India.*

Introduction: Treating severe hyponatremia in liver cirrhosis is challenging. Hypertonic saline and vaptans can be unsafe and cost prohibitive. It needs ICU for close monitoring. Urea given orally can be safe in treating patients with hyponatremia with SIADH. Its role in treating hyponatremia in liver cirrhosis is not established. We present our experience in treating one such patient successfully.

Case Description: A 58-yr-old female with liver cirrhosis from alcoholism and hepatitis C infection was admitted with hypotension, tense ascites and shortness of breath. Her chemistries revealed a sodium of 120 mmol/L, total protein 7g/dl and albumin 2.5 g/dl, BUN 3 mg/dl and creatinine of 0.4 mg/dl. AST 146 U/L, ALT 57 U/L and a bilirubin of 2.8 mg/dl. Urine sodium was <5 mmol/L and osmolality was 366 mOsm/kg. Therapeutic paracentesis of 6 liters performed on the day of admission and 4.25 L on 3rd day and was started on urea15 grams bid. Her sodium level was monitored frequently. On day 3 her sodium was 126 mmol/L and she was discharged on day 5 when it was 128 mmols/L.

Discussion: Hyponatremia can be caused by several conditions. The treatment in most conditions includes elimination of free water, free water restriction or deficient hormones replacement in adrenal insuficiency and hypothyroidism. Hyponatremia is frequently seen in patients with ascites secondary to advanced cirrhosis and portal hypertension. The development of ascites in patients with cirrhosis with portal hypertension and systemic vasodilation leads to activation of the sodium-retaining neurohumoral mechanisms, which include the renin-angiotensin- aldosterone system, sympathetic nervous system, and release of antidiuretic hormone (ADH). The net effect is the avid retention of sodium and water to compensate for the low effective circulatory volume resulting in worsening of ascites. Salt and water restriction alone may not be effective and hypertonic saline and vasopressin receptor (V2R) antagonists' use can be costly and potentially lethal from osmotic demyelination. We conclude that urea is a novel option for treating hyponatremia. It may eliminate the risk of osmotic demyelination unlike with hypertonic saline and V2R. It is an endogenous product of amino acid metabolism, is cost effective in treating hyponatremia of liver cirrhosis and hence should be utilized more frequently. Controlled trials are needed.

PUB192

An Intricate Balance: Co-Existing Types 1 and 4 Renal Tubular Acidosis (RTA)

Gaayathri Krishnan,[1] Dylan Thibaut,[2] Robert C. Wood,[2] Muhammad A. Shahzad,[1] Fernando M. Abanilla.[1] *[1]AdventHealth, Sebring, FL; [2]Lecom Health, Bradenton, FL.*

Introduction: Renal tubular acidosis (RTA) is a group of conditions that affect a kidney's ability to maintain acid-base balance despite unaltered glomerular function. As per studies, type I (distal) RTA and type IV (hyperkalemic) RTA are rare conditions in less than 1 per 10,000 people. We illustrate a unique case where type I and type IV RTA co-existed, and treatment of type IV RTA uncovered an underlying type I RTA.

Case Description: An 88-year-old male presented with fatigue and lightheadedness. His history included metastatic melanoma treated with nivolumab, polymyalgia rheumatica, Sjogren's syndrome on chronic steroids, and hypertension on lisinopril. He was admitted with hyponatremia and hyperkalemia. Labs showed normal anion gap metabolic acidosis (NAGMA), positive urinary anion gap (UAG), and acidic urinary pH. On questioning, he stated that he reduced his steroid dose to one-fourth. Low cortisol, a positive cosyntropin test, normal aldosterone, and high renin confirmed diagnosis of adrenal insufficiency provoked by acute steroid cessation. He was treated and discharged. Electrolyte abnormalities resolved, but NAGMA persisted. A few months later, he was readmitted with hypokalemia, contrasting labs, alkaline urine pH, and a positive UAG. NAGMA persistence suggested type I RTA. (Fig 1) Distal RTA was deemed secondary to his Sjogren's syndrome or nivolumab; it was treated with potassium citrate.

Discussion: Type I RTA, associated with autoimmunity, is caused by impaired distal convoluted tubule hydrogen ion excretion leading to high urine pH, a positive UAG, and hypokalemia. Type IV RTA is linked to hypoaldosteronism, aldosterone resistance, and renin-angiotensin-aldosterone blocking agents. It leads to low urine pH, hyperkalemia, and a positive UAG. Cortisol, like aldosterone, acts on mineralocorticoid receptors of the collecting ducts to activate the epithelial sodium channels (ENAC) and renal outer medullary potassium channels (ROMK) to facilitate electrolyte movement. We postulate that his type IV RTA was potentiated by exogenous steroid withdrawal while on lisinopril; once treated, the underlying baseline type I RTA was uncovered.

Table 1. Pertinent Laboratory Findings

		Baseline	First Admission Day 1	First Admission Day 2	Second Admission Day 1
Serum					
	Sodium (mmol/L)	127	123	129	126
	Potassium (mmol/L)	3.4	5.2	5.5	3.5
	Chloride (mmol/L)	104	112	106	109
	Bicarbonate (mmol/L)	20	19	21	13
	Anion Gap	10	8	9	9

	pH	None	<5	<5	>6.5
	Urine Anion Gap	None	Positive	Positive	Positive

PUB193

Severe Anion and Non-Anion Gap Metabolic Acidosis in a Patient with Hereditary Periodic Paralysis

Jessica K. Cobb,[1] Claude Bassil,[2] Lachlan P. Shiver,[1] Jay V. Dominguez,[2] Atif Siddique.[2] *[1]USF Morsani College of Medicine, Tampa, FL; [2]Tampa General Hospital, Tampa, FL.*

Introduction: Hypokalemic periodic paralysis (HPP) is a disorder of ion channels that may cause individuals to experience paralytic episodes. Treatment depends on the severity of the attacks. Patients are encouraged to increase potassium intake. Carbonic anhydrase inhibitors have been shown to be effective in reducing attacks in some patients.

Case Description: The patient is a 19-year-old female with a history of HPP (on Diamox, recently increased) who presented with a one-week history of increasing weakness with subjective fevers, night sweats, chills, dyspnea, wheezing, and diarrhea. On admission, the patient was hemodynamically stable with tachycardic. Labs included a respiratory viral panel positive for parainfluenza, high anion gap metabolic acidosis (HAGMA) (7.19/24/50/9, AG 21), and normal potassium (3.6). Laboratory studies suggested starvation ketosis with ketonuria and glucose of 68. Subsequent laboratory workup demonstrated alkaline urine (pH 8.0) and potassium drop to 2.3, indicating possible renal tubular acidosis type two (RTA2). HAGMA was secondary to ketoacidosis and non-anion gap metabolic acidosis (NAGMA) secondary to diarrhea and RTA2 due to chronic Diamox use. Treatment included potassium replacement progressively as a priority before normalizing her acidosis which had the potential to make her life-threatening hypokalemia worse. Therefore, a total of 200-270 per 24 hours mEq of KCL was given and a decision was made to give oral sodium bicarbonate since the bicarbonate drip at our hospital contains d5w which can make her hypokalemia worse. A renal function panel was ordered every four hours initially, observing for rebound hyperkalemia. EKGs were completed twice a day. Diamox was resumed at a lower dose once the patient stabilized. The patient's weakness continued to improve until back at baseline.

Discussion: This case underlines the complexity of managing a combined HAGMA/NAGMA in an HPP patient. The priority in managing similar patients should be carefully correcting hypokalemia in an ICU setting with EKG monitoring and immediately holding Diamox. Once the hypokalemia is corrected, start oral bicarbonate with IV fluids and oral feeding to reverse the ketosis. Careful correction of potassium and metabolic acidosis was necessary as the base defect was large, but treatment with bicarbonate could worsen hypokalemia.

PUB194

SLC34A3 Mutation: A "Non-Garden Variety" of Hypercalcemia

Joseph Mahalli,[1] Tuan Nguyen,[1] Phuong-Chi T. Pham,[1] Anita Kamarzarian,[1] Golriz Jafari,[1] Phuong-Thu T. Pham.[2] *[1]Olive View-UCLA Medical Center, Los Angeles, CA; [2]Ronald Reagan UCLA Medical Center, Los Angeles, CA.*

Introduction: Hypercalcemia is a common reason for renal consultation. Measurements of parathyroid hormone (PTH), PTH-related peptide, 1,25$(OH)_2$ vitamin D (1,25D), and serum phosphorus are typically ordered. 1,25 hypervitaminosis prompts routine investigation for ingestion, granulomatous disease, or lymphoproliferative disorders. When a source is not obvious, further genetic testing should be considered.

Case Description: 60-year-old woman with diabetes mellitus type 2, hypertension, hyperlipidemia, chronic osteoarthritis, chronic pelvic pain, and history of rheumatic heart fever was referred for intermittent hypercalcemia, ranging between 9.9-11.2 mg/dL. Medications: amlodipine, atorvastatin, fenofibrate, glimerpiride, metformin, metoprolol, magnesium oxide, loratidine Vital signs: height 160 cm, weight 85.5 kg, blood pressure 145/62 mmHg, pulse 72 bpm, 36.2°C Physical exam: within normal limits Other laboratory findings: Serum phosphorus ranges between 2.6-3.8 mg/dL (2.4-4.7 mg/dL), albumin 4.1 g/dL (3.5-4.8 g/dL), PTHrp 16 pg/mL, (14-27 pg/mL), 1,25D_3 ranges between 67-82 pg/mL (18-72), PTH ranges between 28-49 pg/mL (15-65). 24-hour urine study: calcium 645 mg, creatinine 1.4 g, sodium 280 mmol, phosphorus pending. No bone abnormality of chest or hand radiographs Kidney ultrasound without stones or structural abnormality Genetic testing (Natera, Renasight) revealed heterozygous mutation of SLC34A3 gene.

Discussion: Genetic testing was positive for heterozous mutation of SLC34A3, a gene encoding the renal sodium-dependent phosphate cotransporter 2c (NaPi-IIc). In this condition, phosphaturia is thought to increase 1,25D synthesis to increase gastrointestinal (GI) absorption of phosphorus. The high 1,25D level simultaneously enhances GI aborption of calcium, causing hypercalcermia and corresponding hypercalciuria. At the time of this writing, urine studies for phosphaturia is pending. Presence of hyperphosphaturia would confirm the etiology of hypercalcemia as hereditary hypophosphatemic rickets with hypercalciuria, in which case, treatment would be phosphorus supplementation. In current heterozygous case, patient only develops abnormal calcium and phosphorus profile without associated bone involvement. Hypercalcemia has a wide differential diagnosis. A thorough search for its cause is warranted for direct and specific therapy.

PUB195

When History Repeats Itself: Metformin-Associated Lactic Acidosis

Pooya Zardoost, Blake Leeds, Sana Tyabuddin, Henry L. Wehrum. *OhioHealth, Columbus, OH.*

Introduction: Metformin associated lactic acidosis (MALA) is a fatal phenomenon that clinicians often overlook. However, predisposing comorbidities such as CKD can make the patient more vulnerable to MALA, especially if the metformin dose is not appropriately adjusted. We present a patient with a suspected history of CKD, prior admission for suspected MALA, on high dose metformin who presented with severe lactic acidosis and acute kidney injury requiring dialysis.

Case Description: A 70-year old female with a history significant for diabetes and hypertension presented with nausea, vomiting, fatigue and confusion. Chart review showed that she had several hospitalizations before that were complicated by AKI requiring dialysis, including one in which MALA was suspected. Unfortunately, her home metformin dose (1000 mg BID) was never adjusted. Her GFR the previous year ranged from 30 to 60 ml/min per 1.73 meters squared, and creatinine remained around 1.1 mg/dL. Vitals on admission were 113/55 mmHg, heart rate of 111 bpm, respiratory rate of 28, and temperature of 97.1 F. On physical exam she was alert and oriented, appeared uncomfortable and had tachycardia. Creatinine was 6.2 mg/dl, with blood urea nitrogen of 40 mg/dL, lactic acid of 18 mmol/L, beta-hydroxybutyrate of 1.8 mmol/L, bicarbonate of 6 mmol/L, anion gap of 37 mmol/L, and initial pH of 6.63. She was initiated on maintenance fluids and sodium bicarbonate infusion, but continued to deteriorate, with lactic acid peaking at 40 mmol/L and she was intubated and transferred to the ICU. Her hospitalization was further complicated by shock requiring pressors and steroids. She was started on continuous renal replacement therapy. Within 24 hours her lactic acidosis resolved, her mentation improved, and she was liberated from the mechanical ventilator. Her home metformin was discontinued.

Discussion: While our patient was never officially diagnosed with CKD, there are several factors that raise suspicion for her having this chronic illness. Her average GFR the previous year, history of hypertension, diabetes, as well as prior episodes of AKI requiring hemodialysis warranted an evaluation for CKD. Patients who survive AKI have been shown to have an association with developing CKD. In the setting of recurrent admissions for AKI and CKD risk factors, providers should have a lower threshold for investigating potentially nephrotoxic medications.

PUB196

Drug-Induced Fanconi Syndrome Presenting as Chronic Constipation: A Well-Known but Forgotten Entity

Ramsha Riaz, Deepika Jain. *Jersey City Medical Center, Jersey City, NJ.*

Introduction: Fanconi syndrome is a proximal renal tubular dysfunction characterized by renal wasting of electrolytes and solutes. Acquired Fanconi Syndrome is described in the context of various exogenous toxins, drugs, and systemic diseases. We present a case of long-standing constipation treated with a seemingly simple solution by identifying an often-ignored underlying etiology.

Case Description: This is a 59-year-old South Asian female with history of hypertension, diabetes, stage 3a chronic kidney disease, and chronic hepatitis B and C infection who presented to the hospital with complaint of persistent abdominal discomfort due to constipation for 3 weeks. She had prior hospitalizations for the same complaint. Her home medications included tenofovir disoproxil fumarate (TDF) which she had been taking for 10 years amongst others. Lisinopril and metformin were recently discontinued owing to a previous hospitalization for acute kidney injury. At presentation, labs were significant for severe hypokalemia (K 2.3), unresponsive to aggressive oral and intravenous potassium supplementation, mild hyponatremia (Na 131), hypophosphatemia (PO4 1.9), hyperchloremia (Cl 113), and acute on chronic renal dysfunction with BUN/Creatinine 20/2.17 mg/dL. Urinalysis showed a glucose of >1000 mg/dL and protein of 100 mg/dL. Further work-up of hypokalemia revealed a trans-tubular potassium gradient (TTG) of 5-6, indicating renal wasting. Tenofovir was suspected to be the culprit causing renal tubular acidosis and electrolyte derangements precipitating chronic constipation. Patient was switched to Entecavir after consultation with infectious disease. Follow-up during subsequent months showed correction of electrolyte abnormalities without the need for supplementation and resolution of constipation.

Discussion: Fanconi syndrome is a well-established entity, with a known association with Tenofovir. Clinicians often overlook the pathology leading to unnecessary work-up and prolongation of symptoms. In our case, simply discontinuing the drug helped correct the electrolyte derangements and prevent subsequent hospitalizations due to constipation. Physicians should closely monitor patients on medications known to induce Fanconi and keep this syndrome in the differential when dealing with multiple electrolyte imbalances and disproportionate glucosuria. Early identification can prevent progression of disease.

PUB197

Anion Gap Metabolic Acidosis in Chronic Acetaminophen Use: An Ongoing Conversation

Juan J. Cintrón-García, Sylvester Barnes IV. *Loyola University Health System, Maywood, IL.*

Introduction: In the inpatient setting high anion gap metabolic acidosis (HAGMA) is a common finding. Clinical approach to address HAGMA tends to focus on common etiologies such as lactic acidosis, diabetic ketoacidosis, uremia and others, usually overlooking acetaminophen toxicity as the underlying problem. Accumulation of 5-oxoproline has been described as causing HAGMA in chronic use of acetaminophen (APAP).

Case Description: 74yo female with medical hx of HTN, SLE, DM2, end-stage renal disease (ESRD) on hemodialysis (HD) Admitted for CABG and severe aortic stenosis repair. Last HD had been a day prior to surgery and resumed on POD1 as continuous veno-venous hemofiltration (CVVH). Scheduled medications included APAP, aspirin, heparin, hydroxychloroquine, pantoprazole, polyethylene glycol. On laboratory values Na 135 mEq/L, K 4.6 mEq/L, Cl 99 mEq/L, HCO_3 25 mmol/L, BUN 22 mg/dL, creatinine 3.02 mg/dL, glucose 88 mg/dL Ca 9.6 mg/dL and PO_4 4.5 mg/dL. Post-op complicated with altered mental preventing extubation, enterococcus bacteremia with septic shock requiring pressors. Started on ampicillin and cefepime antibiotic therapy, CVVH continued for 26 days. Transitioned to accelerated veno-venous hemofiltration (AVVH) thrice weekly. After AVVH was completed the patient developed metabolic acidosis with a bicarbonate of 16 mmol/L. Arterial blood gases pH 7.29, paO2 183 mmHg, pCO2 level 34 mmHg and bicarbonate level 16 mmol/L. Lactic acid level 0.8 mmol/L and D-lactic acid undetected. Due to acidosis CVVH was restarted on POD28. The following day bicarbonate was 24 mmol/L.

Discussion: Medication review showed scheduled APAP since prior to admission. There was low concern for ketones as the exogenous source of anions as insulin continued throughout the tube feedings. We inferred the increased HAGMA likely resulted from 5-oxoproline accumulation. APAP was discontinued on POD29, CVVH was discontinued the next day with intermittent HD provided on POD31on a thrice weekly schedule. Holding HD for greater than 48 hours, bicarbonate nadir was 21 mmol/L. Chronic acetaminophen use and 5-oxoproline should be considered in HAGMA when more common etiologies have been addressed. The use of RRT complicated the picture and delayed diagnosis. Most reported cases have been females with chronic medical conditions including renal insufficiency, malnourishment, sepsis.

PUB198

Unsettling Lactate Levels: A Hint Toward Metformin Toxicity

Loai Dweik, Pratik Rath, Natthavat Tanphaichitr. *Cleveland Clinic Akron General, Akron, OH.*

Introduction: Metformin is a common and safe antidiabetic agent to treat diabetes mellitus (DM). Metformin-associated lactic acidosis (MALA) is a rare condition yet has high clinical deterioration and mortality rates. The following case illustrated a patient presenting with encephalopathy, found to have metabolic acidosis due to metformin toxicity.

Case Description: A 51-year-old male with a past medical history of atrial fibrillation, congestive heart failure, DM type II, hypertension, hyperlipidemia, and obesity presents with encephalopathy and respiratory distress. Physical exam was remarkable for somnolence, scleral icterus, bilateral lower limb edema and venous stasis dermatitis. His baseline serum creatinine levels were in the 1.10-1.20mg/dL range. Relevant labs at presentation revealed serum creatinine 2.77 mg/dL, blood urea nitrogen 34 mg/dL, potassium 8.3 mmol/L, bicarbonate 8 mmol/L, anion gap 39 mmol/L, and lactate 22.3 mmol/L. Metformin level was at 9.0 mcg/dL. Radiological workup was unremarkable. Patient went into circulatory shock requiring vasopressor support and mechanical ventilation. Continuous renal replacement therapy (CRRT) was initiated for severe hyperkalemia and acidosis. Sodium bicarbonate infusion was started to improve acid-base dyscrasia. He was transitioned to hemodialysis after hemodynamic stability was achieved. Hospital course was complicated with hospital aquired pneumonia and acute liver failure. After prolonged intubation, tracheostomy and percutaneous endoscopic gastrostomy were performed with no immediate complications. He continued to improve and remained stable, allowing discharge to a long term acute care hospital.

Discussion: According to the literature, therapeutic plasma metformin level ranges between 0.1 and 4 mg/ml, higher metformin levels are proposed to be a cause of lactic acidosis. Risk factors include individuals with decreased renal function, impaired hepatic metabolism and circulatory abnormality. Metformin stimulates lactate conversion and promotes substrates for lactate production, owing to unsettling lactate levels when it accumulates. MALA presents with nonspecific symptoms which can lead to delays in diagnosis. It is imperative that dialysis is promptly initiated for treatment, clearing metformin accumulation. Early suspicion and metformin levels in specific patients can lead to favorable outcomes.

PUB199

Hypokalemia-Induced Nephrogenic Diabetes Insipidus in an Adult with Severe Hyponatremia: A Case Report

Arpit Jain,[1,2] Matthias Bergmann,[1,2] Ruth Schulman.[1,2] *[1]St Elizabeth's Medical Center, Brighton, MA; [2]Tufts University School of Medicine, Boston, MA.*

Introduction: Acquired nephrogenic diabetes insipidus (DI) can be due to kidney disease, medication adverse effects, or electrolyte derangements, such as hypokalemia. We report a case of acquired nephrogenic DI due to hypokalemia in the setting of severe hyponatremia.

Case Description: A 54-year-old man with hypertension and bipolar disorder on lithium therapy presented with nausea, vomiting, and fatigue for several days. Initial laboratory work showed metabolic alkalosis with venous blood pH of 7.61, serum bicarbonate of 41 mmol/L, serum sodium of 102 mmol/L, serum potassium of 2.0 mmol/L, and serum chloride of 60 mmol/L. Urinalysis showed low osmolality of 60 mOsm/kg and sodium of <20 mmol/L. The hyponatremia was attributed to a combination of psychogenic polydipsia and decreased solute intake and was treated

with fluid restriction. Subsequent hyponatremia overcorrection (>12mmol/L per day) with a continued urine output of 7-8 L/day was managed with dextrose 5% in water and desmopressin. Interestingly, urine osmolality remained at 63 mOsm/kg and did not increase after several doses of desmopressin, consistent with the diagnosis of nephrogenic DI, initially attributed to lithium use. However, after normalization of serum potassium, spontaneous urine concentration to 360 mOsm/kg was observed (Figure 1), suggesting hypokalemia-induced nephrogenic DI.

Discussion: This case illustrates the critical role that potassium plays in the urine concentrating ability of the kidney. Adequate serum potassium levels are necessary for the kidneys to respond to desmopressin, which is an essential tool in treating hyponatremia overcorrection. Rapid potassium repletion is often initially delayed to avoid hyponatremia overcorrection and its dramatic complications. However, hypokalemia can lead to acquired nephrogenic DI which can worsen hyponatremia overcorrection.

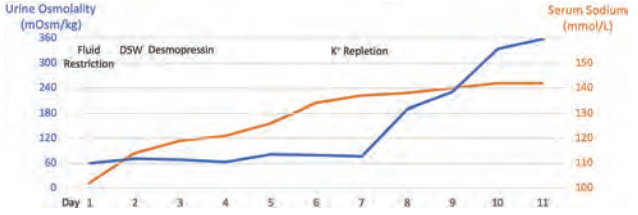

Figure 1. Serum sodium and urine osmolality trend over the course of the treatment. The urine osmolality did not increase with desmopressin administration. However, with potassium repletion, the urine osmolality started rising, suggesting a diagnosis of hypokalemia-induced nephrogenic diabetes insipidus.

PUB200

A Rare Case of Zonisamide-Induced Distal Renal Tubular Acidosis (RTA)

Sanjana Nethagani, Neeharika Muddana. *Camden Clark Medical Center, Parkersburg, WV.*

Introduction: Zonisamide is a commonly used anti-epileptic drug which has been associated with side effects such as constipation and nausea. It has also been reported to cause distal renal tubular acidosis in the past but this is an exceedingly rare occurance. Upon review of literature, only one documented case report has been published showing the association between zonisamide use and RTA. In this case, we aim to further the knowledge of this seldom seen side effect.

Case Description: A 28 year old male with history of autoimmune limbic epilepsy and temporal lobectomy on zonisamide was admitted to our institution after being referred by PCP for hypokalemia and rhabdomyolysis. Prior to admission, he noted a myriad of symptoms such as myalgias, unsteady gait, and nausea. BMP on admission revealed potassium level of 1.6, serum chloride 115 and serum bicarbonate 2. EKG changes associated with severe hypokalemia were noted. He was started on continuous potassium replacement with IV as well as oral supplements. Despite adequate correction, his potassium level continued to drop and remained under 2 mmol/L. Workup showed normal serum aldosterone level. Serum and urine electrophoresis showed no evidence of monoclonal gammopathy. Renal ultrasound, CT abdomen and CT chest were all normal with no anatomical abnormalities or masses. Urine anion gap was inconclusive- neither significantly positive nor negative. Spot urine protein/creatinine ratio was 37.6 mg/g which was suggestive of urinary potassium losses. After ruling out other causes of potassium depletion, his medication list was reviewed and zonisamide was identified as a potential cause of hypokalemia. He was tapered off zonisamide and started on alternate therapy. He was eventually stablizied and discharged to home. Upon follow up labs in 6 weeks, his potassium had normalized and he was asymptomatic which further proved that zonisamide was the cause of distal RTA and severe hypokalemia.

Discussion: This case highlights the importance of thorough history and medication review which aids in diagnosing such challenging presentations. Although there is not much literature to support, zonisamide can cause RTA as shown in our case. Other anti epileptic agents have been studied such as topiramate which are implicated in RTAs, suggesting that agents previously which have not been studied might also have the potential for such side effects.

PUB201

Pseudonormokalemia

Douglas R. Farrell, Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Thrombocytosis is a well known cause of "pseudohyperkalemia", whereby measured serum potassium is falsely elevated due to release from platelets after clotting once collected, which can be overcome by the addition of heparin. In clinical practice, heparinized tubes are used after identification of hyperkalemia to rule out pseudohyperkalemia. Rarely is this considered in the setting of normal serum potassium, but is still an important consideration in patients with thrombocytosis as a normal value may represent a total body deficit in potassium, known as "pseudonormokalemia". We present the case of a patient with thrombocytosis and normal measured serum potassium who developed metabolic alkalosis during diuresis, though found to have significant hypokalemia after heparinizing the collection tube.

Case Description: Our patient was a 53 yo man with HTN admitted to the cardiothoracic service for CABG after admission for STEMI. His course was complicated by AKI for which the nephrology consultation service was involved. His kidney function recovered during his admission, though with hypervolemia for which he was diuresed with IV furosemide. During his course he developed reactive thrombocytosis, and rising serum bicarbonate with apparent normal serum potassium (Figure1). After heparinizing potassium collection, significant hypokalemia (2.9 MEQ/L) was revealed in a patient with sensitive myocardium.

Discussion: We report the case of "pseudonormokalemia" in a patient diuresed with furosemide with concomitant reactive thrombocytosis. We believe this case highlights an important consideration in the evaluation of patients at risk for hypokalemia, and to consider use of heparinized collections in those with thrombocytosis regardless of their serum potassium level.

Laboratory test	T-3	T-2	T-1	T
Platelet Count (10^3/uL)	672	672	933	1,099

Trimethoprim-Sulfamethoxazole-Associated Severe Hyponatremia

Salman Bhutta, Abhishek Nimkar, Hitesh H. Shah. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Trimethoprim-Sulfamethoxazole (TMP-SMX) is recommended as first line therapy for the treatment of *Pneumocystis Jirovecii* pneumonia. Although described in the literature, hyponatremia remains a rare complication of TMP-SMX treatment. Here, we present a case of severe hyponatremia in a hospitalized patient following treatment with high-dose intravenous TMP-SMX.

Case Description: 65-year-old female with metastatic lung cancer presented to our hospital for shortness of breath and fatigue. Pt. received a course of chemotherapy 4 days prior to presentation. Pt. was found to have *Pneumocystis Jirovecii* pneumonia and was initiated on high-dose intravenous TMP-SMX (430 mg trimethoprim and 86 mg SMX twice daily). SNa was 137 mmol/L (normal range 135-145 mmol/L) prior to initiation of TMP-SMX treatment. SNa subsequently decreased to 129 mmol/L the day after and decreased further to 118 mmol/L 3 days later. CT chest showed diffuse bilateral ground glass opacities concerning for infectious process vs pulmonary edema. Patient received intravenous furosemide therapy. SNa however decreased further to 114 mmol/ L. Hyponatremia work up revealed low serum osmolality of 250 mosm/kg, elevated urine osmolality of 481 mosm/kg, and inappropriately elevated urine sodium of 45 mmol/L. Patient was initiated on 3% hypertonic saline infusion. SNa improved but remained stable at 121 for the next 2 days. Intravenous TMP-SMX was subsequently discontinued. SNa gradually improved to 129 mmol/L, 2 days after discontinuation of TMP-SMX. Over the next few days, patient clinical condition worsened and died during the hospital stay.

Discussion: Patients receiving chemotherapy are at an increased risk for serious bacterial, fungal, and viral infections. Our patient was found to have *Pneumocystis Jirovecii* pneumonia. Treatment with high dose intravenous TMP-SMX resulted in severe acute hypo-osmolar hyponatremia. While the exact mechanism of hyponatremia secondary to TMP-SMX use remains unclear, inappropriate secretion of anti-diuretic hormone and renal salt wasting have been proposed in the past. Hyponatremia improved significantly in our patient soon following the discontinuation of TMP-SMX treatment. Clinicians should be aware of this potential and reversible adverse effect of this agent.

PUB203

Oxcarbazepine-Induced Hyponatremia

Samuel B. Lassiter,[1] Brandon T. Dunmyre.[2] *[1]Lake Erie College of Osteopathic Medicine, Erie, PA; [2]Allegheny Health Network, Pittsburgh, PA.*

Introduction: Antiepileptic medications are well known to induce hypoosmotic hyponatremia, however, the precise mechanism of action remains under debate, ranging from SIADH induction to psychogenic polydipsia. Unfortunately, these agents are often overlooked and continued upon hospital admission. We describe a patient who developed hypoosmotic hyponatremia in setting of recently started oxcarbazepine.

Case Description: 54F pmhx seizure disorder, hypertension, and COPD presented with the chief complaint of progressive shortness of breath and refractory nausea due to community acquired pneumonia and viral gastroenteritis, respectively. Chemistry panel

showed serum sodium 121 mmol/L (138 mmol/L one month prior), serum osmolality 262 mOsm/kg, potassium 4.1 mgl/dL, BUN 17 mg/dL, and serum creatinine 0.9 mg/dL. Vital signs showed blood pressure 128/73 mmHg and heart rate 72 BPM. Physical exam revealed euvolemic volume status with lack of altered mentation. Urine studies, obtained prior to fluid administration, revealed urine sodium 42 and urine osmolality 500 suggesting SIADH attributed to pneumonia and nausea. She was started on a 1.5L daily free water restriction and urea 15 mg BID and admitted to ICU for sodium monitoring. Home medications, including oxcarbazepine, were continued upon admission. The serum sodium failed to improve over the first 36 hours despite increasing urea powder to 30 mg BID and increasing fluid restriction to 1.2L. Medication review revealed continuation of home oxcarbazepine which, per patient history, was initiated three weeks prior to hospitalization. Oxcarbazepine, urea powder, and fluid restriction were stopped and neurology service consulted for implementing an alternative anti-epileptic agent. The serum sodium improved spontaneously, without additional intervention, from 121 mmol/L to 138 mmol/L, over the proceeding 72 hour time interval.

Discussion: Oxcarbazepine can result in hyponatremia refractory to the common therapeutic strategies used to treat SIADH. Our case illustrates the importance of reviewing the outpatient medication list as many pharmacologic agents can be continued upon admission, without discretion, ultimately contributing to refractory electrolyte abnormalities. Additionally, we must consider alternative etiologies, even in the setting of known SIADH stimuli, when common clinical practices fail to result in hyponatremia improvement as an unidentifiable etiology may be present.

PUB204

Salt Is Good: Correction of Hyponatremia in Heart Failure with Dietary Sodium

Ogbugo Emeh, Gabriela Narowska, Sheetal Koul, Jean Lee, Ziauddin Ahmed, Estefania Oliveros. *Temple University, Philadelphia, PA.*

Introduction: Hyponatremia is the most common electrolyte imbalance in patients with acute decompensated heart failure. It is associated with increased mortality, hospitalizations and can pose challenges with management of volume overload. The mechanisms of hyponatremia in heart failure are high levels of antidiuretic hormone coupled with low glomerular filtration rate and the use of loop and thiazide diuretics. We present a case highlighting the complexity of sodium balance in acute decompensated heart failure.

Case Description: A 65-year-old female with CHF with preserved EF (60-65%), pulmonary hypertension, CAD, Type II diabetes, atrial fibrillation, CKD, presented with acute decompensated heart failure and volume overload. Diuresis was started with bumetanide on day 1 of the hospitalization. Chlorthalidone was added on day 5. This was switched to Metolazone on Day 7. On admission, sodium was 134 mmol/L and down trended to a low of 121 mmol/L on hospital day 13. This was accompanied by significant nausea and vomiting. Despite strict free water restriction and a diuretic holiday, hyponatremia persisted. She was then encouraged to eat ramen (2167 mg Na per serving) and given salt tablets in addition. Free water restriction was continued as well and so were the loop diuretics. Thiazide diuretics were held. Serum sodium subsequently improved to 131 mmol/L with improvement in symptoms. She was discharged in a euvolemic state on a home regimen of bumetanide and oral salt.

Discussion: We present a case of hypotonic hyponatremia in acute decompensated heart failure. The first line management of hyponatremia in heart failure is diuresis and dietary sodium restriction. However, hyponatremia may be induced or worsened in these patients by multiple mechanisms including SIADH- like physiology and use of thiazide diuretics. In such cases, adherence to a sodium restricted diet while on diuretics may worsen hyponatremia. Increased access to dietary salt with concomitant free water restriction may correct this problem as demonstrated in our patient. Using dietary sources of sodium may work just as effectively as giving hypertonic saline (1770 mg Na per 150 ml bolus). Further studies are needed to elucidate the underlying mechanisms and reproduce similar results on a larger scale.

PUB205

Opening the Gates: Tolvaptan for Chronic Hyponatremia

Caleb S. Pacheco-Molina, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera, Jeaneishka M. Rivera Rios, Maria E. Rivera. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Hyponatremia is a well-studied electrolyte imbalance, and despite established guidelines for its management, it is often difficult. In patients with CHF, hyponatremia is a predictor of death, which makes it important to treat promptly and effectively.

Case Description: A 63-year-old male with a past medical history of CKD stage 2, atrial fibrillation, heart failure, mitral valve replacement, aortic aneurysm repair, and hypothyroidism was admitted with a left hip fracture secondary to a ground-level fall, COVID-19 pneumonia, and severe hyponatremia with mild hypokalemia. Upon initial evaluation, the patient was disoriented with signs of volume depletion, including dry oral membranes, and decreased capillary refill. Laboratory evaluation was remarkable for a sodium level of 114 mEq/L, serum osmolarity of 251 mOsm, and urine sodium of less than 10 mEq/L, consistent with hyposmolar hypovolemic hyponatremia. After a 24-hour trial of isotonic fluid and potassium repletion, the serum sodium improved to 117 mEq/L, and potassium levels were corrected. 0.9% Normal saline was continued with improvement of sodium to 122 mEq/L in a 48-hour period. At this point, the patient's mental cognition improved, he was alert and oriented. Over the next 72 hours, sodium levels remained unchanged, and the patient started developing signs of volume overload. Isotonic fluids were discontinued, and a fluid restriction diet plus diuretic therapy was initiated. Volume status improved, but with only mild changes in sodium levels. To correct the sodium level to at least 130 mEq/L for the patient to undergo surgery for his fractures, a trial of tolvaptan 7.5 mg PO daily was initiated, resulting in a rise in serum sodium to 127 mEq/L in the first 24 hours, and a level of 130 mEq/L in 72 hours. Diuretic therapy was discontinued and tolvaptan was continued for the remainder of the hospitalization, with the sodium level reaching 134 mEq/L by day 26 of therapy. He was able to undergo surgery, tolvaptan was discontinued, and the patient was discharged home with normal sodium levels.

Discussion: Tolvaptan is a breakthrough in the treatment of hyponatremia, particularly in patients with SIADH, but its use in patients with HF has also been of great support. This case is an example of its effectiveness in this population.

PUB206

Hypo-Hypercalcemia of Rhabdomyolysis

Mohammad W. Abushawer,[1] Sandeep R. Sasidharan,[1] Tahir A. Jatoi,[1] Firas Kadurei,[2] Moro O. Salifu.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]New York City Health and Hospitals Coney Island, Brooklyn, NY.*

Introduction: Rhabdomyolysis (RD) is the breakdown of skeletal muscle, with release of intracellular contents including electrolytes and enzymes, which can result in AKI. Hypocalcemia is commonly associated; however, hypercalcemia after initial hypocalcemia has been reported. The pathogenesis of hypercalcemia remains unclear with multiple theories. We report a case of hypo-hypercalcemia associated with cocaine induced rhabdomyolysis.

Case Description: A 42-year-old male with a history of polysubstance abuse presented with septic shock along with cocaine intoxication leading to severe muscle damage, cardiac arrest, and oliguric AKI, requiring HD. On admission, CK level was 103510 U/L, BUN 28 mg/dL Creati 2.8 mg/dL, and Corrected Ca 6.7 mg/dL. 1 week after the admission, his Ca level started to normalize; However, after 20 days he developed hypercalcemia with Ca values ranging from 10.3 to 12.8 mg/dL with PTH 16.3 pg/mL and 1,25(OH)2 D <8.0 pg/dL. His AKI did not show any improvement with a GFR < 15 mL/min, still oliguric and eventually became HD dependent. The hypercalcemia was managed with intermittent doses of calcitonin when the level rose above 12.0 mg/dL. After 1 month, his clinical condition started to deteriorate, and he passed away.

Discussion: Disturbance in Ca homeostasis has been observed in cases of rhabdomyolysis-induced AKI. Initial Hypocalcemia is due to sequestration of Ca associated with hyperphosphatemia in the destroyed muscle. Subsequent hypercalcemia may occur during the recovery phase of AKI caused by RD. The pathophysiology of hypercalcemia has remained a subject of debate. Some believed that the pathophysiology of hypercalcemia occurring in the recovery phase of RD induced AKI, was from resorption of Ca from injured muscle and transient hyperpara. However, others believed that the mechanism of hypercalcemia is the dissolution of deposited CaPO4 from the damaged muscles, in which the deposits were shown in the technetium pyrophosphate scan. This case supports the hypothesis that remobilization of calcium deposits from damaged muscle is the main element of delayed hypercalcemia, as the PTH and 1,25(OH)2 D levels were suppressed during the period of hypercalcemia. However, our patient was unique in presentation as his hypercalcemia occurred while on HD as opposed to during renal recovery. We want to increase awareness of this phenomenon with our case report.

PUB207

Octreotide-Induced Hyperkalemia

Mohammad W. Abushawer, Sandeep R. Sasidharan, Tahir A. Jatoi, Fausto R. Cabezas, Mary C. Mallappallil. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Sulphonylurea agents are widely used in the treatment of type II diabetes. Hypoglycemia is a major side effect with renal impairment and long acting SUAs as risk factors. Octreotide is a synthetic somatostatin analog that is a potent inhibitor of growth hormone, glucagon, and insulin and used to treat relapsing or refractory hypoglycemia induced by SUAs.

Case Description: 43-year-old male with obesity, hypertension, diabetes, sleep apnea, heart failure, hyperlipidemia, recent hospitalization for hypoglycemia, CKD 5 nearing dialysis. Presents with asymptomatic hypoglycemia with BS ranging 20-50s for two days not resolved with oral glucose. He had discontinued Semaglutide since last admission and on Glipizide at admission. Vitals were BP 138/80mmHg, Pulse 93 bpm, Temp 97.8 F, Resp 21/min, sat 96% on 3L of NC(85% on RA), BMI 48 kg/m2. Labs significant for K 5.6 MeQ, BUN 52 mg/dl, Creat 8.06 mg/dl, Glucose 45mg/dl, Insulin 7.05mIU/L, Ph 7.24, PCo2 66mmHg, Lactate 1.3mmol/L, U/A had Protein 300, large blood, trace leucocyte esterase, RBC 73, Glucose, ketone, bilirubin, nitrite, WBC, cast were neg. U/S showed bilaterally increased echogenicity and simple renal cysts. After hypoglycemia did not resolve with D5W. He was transferred to ICU for D10 infusion and started on Octreotide SQ. His hypoglycemia resolved but he developed severe hyperkalemia at 7.3 MeQ without EKG changes, which did not resolve with medical therapy. He required HD. His potassium improved but continued HD for CKD5.

Discussion: Octreotide, similar to somatostatin, directly inhibits the release of insulin from the pancreas, preventing rebound hypoglycemia, as compared to dextrose infusions for SUAs overdoses. The mechanism of octreotide induced hyperkaliemia is most likely due to the suppression of insulin release, which impairs cellular potassium uptake resulting in an increased extracellular potassium concentration. While octreotide is primarily metabolized in the liver, some experts suggest that dosage modification may be necessary due to reduced clearance. Although there have only been a few reported cases in the literature, we suspect that hyperkalemia induced by octreotide may be more

prevalent and may be attributed to other factors. Therefore, our case report aims to raise awareness of this potential complication and contribute to a better understanding of octreotide-induced hyperkalemia.

PUB208

The Alkaline Tube: A Dangerous Tide

Javier Apodaca,[1,2] Sabiha M. Khan,[1,2] Ann Hinckley,[3] Spencer Hodgins.[1]
[1]Baystate Medical Center, Springfield, MA; [2]University of Massachusetts Chan Medical School, Worcester, MA; [3]Kidney Care and Transplant Services of New England, West Springfield, MA.

Introduction: Metabolic alkalosis is the most common acid-base disorder in critically ill patients. When severe (pH>7.55) it is associated with significantly increased mortality. Here, we have a critically ill patient in the setting of severe metabolic alkalosis who was treated successfully with hemodialysis (HD). The case highlights the importance of recognizing nasogastric tube (NGT) suction as a source of severe metabolic alkalosis, as well as rapid intervention.

Case Description: An 83-year-old man with HTN, CAD, HFrEF, DM, and CKD IV (baseline Cr 2.6 mg/dL) presented with nausea, vomiting, and abdominal pain. He was found to have SBO and was treated with NGT decompression at an outside hospital. NGT output increased over 4 days up to 7L in 24 hours. Bicarbonate increased to >50mmol/L on day 4 with ABG showing pH 7.63; bicarbonate was estimated at 78mmol/L based on Henderson-Hasselbach equation. He only received NS at 100 mL/h for 4 days despite rising NGT output. He developed anuric AKI with a creatinine of 6.7mg/dL with fatigue, muscle twitching, and tremors. He was sent to the ICU due to recurrent ventricular arrhythmias, then was transferred to our institution for HD due to severe metabolic alkalosis and anuric AKI. Despite the ICU team's attempt to place a dialysis catheter, adequate blood flow for dialysis was not achieved. A new catheter was not placed until the following morning delaying HD for around 12h. Post-HD ABG showed a pH of 7.45 and bicarbonate 33mmol/L. The patient was eventually able to stop dialysis and was discharged.

Discussion: This patient developed severe metabolic alkalosis due to loss of gut HCl. The underlying physiology is a chloride-sensitive alkalosis that may be treated with NS and repletion of potassium, however in the setting of his oliguric AKI, he was unable to secrete adequate bicarbonate. His case illustrates a few important pitfalls; first, high NGT output should have prompted major adjustments to therapy; receiving NS at 100mL/h led to gross undertreatment of his chloride losses. Second was underestimating his acuity upon arrival in the ICU; he had been experiencing significant ventricular arrhythmias and was at high risk for seizures and death, however, the malfunctioning dialysis catheter took more than 12h to replace. This patient ultimately had a good outcome but illustrates common pitfalls that many providers could make in the management of severe metabolic alkalosis.

PUB209

Linezolid-Induced Lactic Acidosis

Gilda M. Portalatin, Natalie N. McCall. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Linezolid is used to treat many gram-positive bacterial infections. Its use has increased with the emergence of many multi-drug resistance organisms. Lactic acidosis is a rare but potentially fatal adverse effect of linezolid. Here we discuss a case highlighting the importance of prompt recognition of Linezolid-induced severe lactic acidosis.

Case Description: A 41-year-old woman with ovarian cancer complicated by severe lower extremity lymphedema presented to the emergency department with worsening bilateral lower extremity swelling and pain after failed outpatient antibiotic therapy. Initial workup included a CT scan of the lower extremities concerning for necrotizing fasciitis. Her course was complicated by septic shock, temporarily requiring pressor support, eventually improving after surgical debridement and antibiotic initiation. She received a 4-week course of Ampicillin/Sulbactam, Minocycline, Linezolid, and Voriconazole based on wound culture results. She continued to have severe metabolic acidosis with elevated lactate levels of upwards of 16mmol/L despite clinical improvement and resolution of septic shock nearly 3 weeks following initial presentation. After other etiologies of continued metabolic acidosis were excluded, Linezolid was promptly discontinued. Hemodialysis was performed to enhance drug clearance. Her lactic acidosis improved after 3 days of renal replacement therapy.

Discussion: Linezolid is a bacteriostatic oxazolidinone that inhibits initiation of bacterial protein synthesis at the 50S ribosome demonstrating activity against multidrug-resistant gram-positive bacteria. Though very rare, type B lactic acidosis is a known (potentially fatal) complication that occurs following impairment of mitochondrial protein synthesis and reproduction. It can occur at any point during the course of linezolid use. Treatment is largely supportive and hemodialysis has been shown to assist in drug clearance in a few documented case reports. As described in the literature, it may take approximately 7-14 days for Linezolid to be eliminated even without evidence of renal dysfunction. Currently, no guidelines exist regarding timing of initiation of hemodialysis. However, we believe hemodialysis should be initiated following suspicion of linezolid toxicity along with prompt drug discontinuation in events of severe metabolic and lactate acidosis, acute renal failure or failure to improve despite supportive care.

PUB210

A Case of Uremic Optic Neuropathy

Ali Shah, Peter Iskander, Chilsia Shafi, Khadijah Sajid. *Wright Center for Graduate Medical Education, Scranton, PA.*

Introduction: Uremia is the accumulation of urea in the blood; typically secondary to retention due to kidney dysfunction. Damage to the optic nerve due to its toxicity can lead to visual defects and eventual blindness. Initial management is treating the underlying cause but may require emergent hemodialysis to rapidly filter out the excess urea.

Case Description: 29 year old male with unknown past medical history presents with bilateral blurry vision. Initial labs confirmed BUN of 166 mg/dl, Creatinine of 27 mg/dl and e-GFR of 2 (ref range: 60-89). CT scan of the abdomen showed bilateral shrunken kidneys. Fundoscopy confirmed findings of optic neuropathy. Inflammatory and autoimmune work up was sent for his glomerulonephritis. Per his labs, he met criteria for CKD stage V and was started on peritoneal dialysis; vision improved after 3 sessions and was discharged in stable condition.

Discussion: Uremia can be caused by retention of waste products in the blood due to kidney dysfunction. Accumulation of uremic toxins in the optic nerve can lead to ischemia and optic nerve damage causing visual disturbances; from blurriness to complete loss. In one study, out of 278 patients studied with CKD, 4.7% were found to have uremic optic neuropathy with prevalence proportional to the extent of renal dysfunction [1]. Another study of 93 patients with end stage renal disease found that incidence of 7.5%; risk factors included age, longer duration of renal failure, and higher serum levels [2]. Cataracts are also common uremic patients. Retinopathy in uremic patients can be caused by various mechanisms including ischemia, hypertension, and diabetic nephropathy [3]. These studies highlight the importance of early recognition and treatment of uremic optic neuropathy in patients with renal dysfunction. Managing the underlying cause of renal dysfunction is the first step. As in our case, hemodialysis is often required to remove uremic toxins and prevent further optic nerve damage. 1. PUB211

Renal/Cerebral Salt Wasting in a Patient with COVID-19

Rohini Singla,[1,2] Adrian J. Baudy.[1,2] Tulane Kidney Beans. *[1]Tulane University School of Medicine, New Orleans, LA; [2]New Orleans VA Medical Center, New Orleans, LA.*

Introduction: Renal salt wasting (RSW), commonly known as cerebral salt wasting (CSW), a less recognized cause of hyponatremia, which has mostly been reported in patients with CNS disease, can also be associated with other medical conditions. Hyponatremia has been reported with COVID-19 infection, mostly multifactorial due to loss of sodium ions in the digestive tract, SIADH, and poor intake. It has only rarely been reported with COVID-19. We report a case of COVID-19 infection-associated hyponatremia due to renal/cerebral salt wasting.

Case Description: A 95-year-old male with a history of dementia, hypertension, hyperlipidemia, stage 3a chronic kidney disease, and prostate cancer presented to the emergency department with cough, sore throat, and a positive home COVID-19 test. Initial workup revealed normal chest X-ray, WBC count of 8.0, serum sodium of 121 mmol/L, potassium of 4.6 mmol/L, chloride of 87 mmol/L, BUN of 20 mg/dL, creatinine of 1.1 mg/dL, serum osmolality of 252 mOsm/kg, urine osmolality of 460 mOsm/kg, urine sodium of 32 mmol/L, cortisol of 14.7 mcg/dL, TSH of 3 uIU/mL, uric acid of 2.6 mg/dL, and fractional excretion of uric acid (FEUric acid) of 12.8%. He had no diarrhea but reported decreased oral intake. He remained mentally alert, had a mild cough, and maintained adequate oxygen saturation on room air. Intravenous fluids (IVF) were administered, improving sodium levels to 126 mmol/L. However, upon discontinuation of IVF, the sodium decreased to 115 mmol/L, eventually improving over several days with the re-initiation of IVF, reaching a level of 133 mmol/L. Repeat FEUric acid remained elevated at 11.97%, and serum uric acid remained low at 3.5 mg/dL. He was discharged with improved laboratory results and remained stable during follow-up visits.

Discussion: Differentiating RSW/CSW from other causes of hyponatremia is important due to different treatment approaches. Both RSW/CSW and SIADH have similar clinical parameters like high urine osmolality and sodium, low serum uric acid, and high FEuric acid initially. However, the FEuric acid improves in SIADH after an improvement in sodium levels but not in CSW. SIADH is usually treated with fluid restriction in addition to other measures. While RSW/CSW is treated with volume repletion as patients have intravascular volume depletion. This case signifies that RSW/CSW should be in the differential diagnosis of patients with COVID-19 and hyponatremia.

PUB212

Hyponatremia Causing Confusion, or Confusion Causing Hyponatremia?

Jaspreet Sian. *Creighton School District 14, Phoenix, AZ.*

Introduction: Hyponatremia can present with vomiting, confusion and sezures. This case discusses hyponatremia caused by LGI1 Associated Limbic Encephalitis.

Case Description: 75 year old female presents after having tonic clonic movements of upper and lower extremities. Physical examination shows a laceration at her temple and alert to self only. Labs show WBC of 14.2 K/uL, Na of 117mmol/L, K of 2.8 mmol/L,

osmolality of 248 Osm/kg H_2O, Urine osmolality of 726 Osm/kg H_2O and urine Na of 74 mEq/L. CT head showed no acute intracranial abnormality. Seizures are attributed to hyponatremia; normal saline at 100 mL/hr was started and patient's Na decreased to 113 mmol/L and she had multiple seizures. Hypertonic saline is started but Na is unchanged. Lumbar puncture is normal. EEG monitoring showed numerous clinical episodes, and she has cognitive impairment, startle trigger, ocular dysfunction and gait dysfunction. MRI brain showed subtle right lentiform nucleus enhancement. CSF is sent out for viral and autoantibody screening and there is anti-leucine rich anti glioma 1 protein (anti-LGI1) present. Solumederol and plasmaphoresis for 5 days is started. Na increases from 113mmol/L to 130mmol/L and patient's neurological symptoms resolves.

Discussion: Limbic Encephalitis affects the amygdala, thalamus hypothalamus and medial temporal lobes of the brain causing behavioral disturbances, changes in personality and cognitive behavior; seizures, and psychiatric symptoms. It is a paraneoplastic syndrome associated with small cell lung cancers, germ cell tumors of the testis and tumors of the ovaries. It can be associated with infections, immunosuppression and autoimmune encephalitis. Auto-antibodies associated with the autoimmune encephalitis include N-methyl-D-Aspartate receptor, glutamate 1 and glutamate 2 receptors, and leucine rich anti glioma 1 protein (LGI1). The severe hyponatremia is because it is expressed in the hypothalamus and has excess release of ADH, which correlates with our patient leading to a picture of syndrome of inappropriate ADH. Additionally, LGI1 is also expressed in the tubules of the kidneys. Treatment is high dose steroids, IVIG, and plasmapheresis. Many develop malignancies and require frequent screening. In conclusion, although confusion and seizures are symptoms of hyponatremia, if it does not resolve with traditional fluids; the confusion can cause hyponatremia and encephalitis needs to be considered.

PUB213

Successful Treatment of a Rare Profound Lactic Acidosis and Anuric AKI due to Metformin-Associated Lactic Acidosis

Ao Wang, Arye Kremer, Subodh J. Saggi, Moro O. Salifu. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Metformin therapy in patients with reduced kidney function can generate toxic levels since these drugs are almost entirely removed by kidney, resulting in lactic acidosis. We report a case of metformin induced lactic acidosis in a patient with AKI.

Case Description: A 73-year-old female with a past medical history of type 2 Diabetes, hypertension, seizure, cardiovascular disease sent from Nursing home for hypotension, hypoglycemia and altered mental status. Her medications included metformin 500mg bid, metoclopramide, risperidone, ondansetron. On exam, blood pressure 92/42mmHg, and O2 saturation 96% on 3L nasal cannula, respiratory 20 breaths/min, Heart rate 53 beats/min, and temperature 35.6 °C. Initial lab workup showed VBG PH 6.9 with Pco2 32mmHg HCO3 6 mmol/L lactic acid 21 mmol/L beta-hydroxybutyrate 6.9 mmol/L, Cr 2.6mg/dL (per family, no history of kidney disease) BUN 90 mg/dL, potassium 5.5 mmol/L, sodium 143 mmol/L, chloride 95mmol/L, glucose 30 mg/dL, WBC 10.86 K/uL which revealed high anion gap metabolic acidosis with compensated respiratory alkalosis and anuric AKI. Serum metformin level was collected and sent. Salicylate level and acetaminophen level is low. Patient was treated with intravenous hydration with NS, bicarbonate therapy and antibiotics for suspected pneumonia without improvement in acidosis hence emergency hemodialysis with minimal ultrafiltration was initiated for possible metformin associated lactic acidosis. After 1 hemodialysis session, bicarb improved to 18 mmol/L, lactic acid 5.2 mmol/L, ABG showed PH 7.24. We repeated hemodialysis next day, bicarb improved to 25 mmol/L without metabolic acidosis and lactic acid improved to 2.4 mmol/L. Patient started to make good urine and Cr improved from 2.6 to 1.2 and normalized 3d after second hemodialysis. Metformin level returned a week later to be elevated at 9.1 mcg/ml with therapeutic range of 1-2mcg/ml.

Discussion: This case illustrates complexity in interpretation of the cause of lactic acidosis in a patient with septic shock and metformin toxicity or a combination of both since there is no additional biomarkers, but also illustrates the need for aggressive treatment of septic shock and early initiation euvolemic hemodialysis support to reduce metformin levels and to correct metabolic acidosis.

PUB214

1,4-Butanediol Overdose: An Unrecognized Toxidrome

Rachel Pinto, Mario Bernaba, Scott Mullaney, Bethany E. Karl, Cynthia Miracle. *University of California San Diego, San Diego, CA.*

Introduction: Butanediol (BD) is an industrial solvent, used for plastic manufacture. Illicit recreational use is associated with central nervous system (CNS) depressant effects ("date-rape drug") and euphoria. Overdose can be lethal, but often unrecognized. We present a case of possible toxic alcohol exposure, turned out to be BD overdose.

Case Description: 43yo man, found obtunded in a mechanical shop. Last seen normal 30 minutes prior, at same location. Field vitals unavailable. On admission: BP 146/97mmHg, HR 53, T33.9°C RR 20, obtunded, myotic pupils, no clonus. Unresponsive to naloxone and flumazenil, then intubated. Gastric aspirate showed a red sweet smelling liquid. Initial labs: Normal CBC Na 141 K 3.3 Cl 98 CO2 17 AG 26 BUN 13 Cr 0.98 Glu 115 Ca 9.0 Alk Phos 110 AST 207 ALT 319 TBili 0.46 Alb 4.3 Lactate 7.4 BHB (-). Vbg pH 7.35 pCO2 34. Acetaminophen, salicylate, EtOH and UDS(-). Labs 2h later were essentially unchanged & EtOH still (-). Measured serum Osm 312 with osmolal gap (OG) of 23. Nephrology consulted for ethylene glycol (EG) poisoning suspicion, fomepizole started. Labs 3h later had lower AG and OG (20 and 11, respectively), inconsistent with EG overdose. Patient extubated on the next day and endorsed ingesting 1,4-BD. EG and methanol levels were negative.

Discussion: *In vivo*, BD is quickly metabolized to gamma-hydroxybutyric acid (GHB), an inhibitory neurotransmitter (GABA B receptor agonist) that causes euphoria and sedation. BD poisoning mimics other toxic alcohols toxidromes, but is not detected on traditional drug screening tests. An increased OG is typically present, and supportive care is the mainstay therapy. No antidote is available. Concomitant ingestion of ethanol increases its toxicity, and the use of EtOH as a competitive substrate for alcohol dehydrogenase is contraindicated. The majority of patients can be managed without dialysis, as GHB has a rapid clearance and short duration of clinical effects (between 2-5h). **Take away lesson:** BD overdose can be lethal. The presence of an increased OG with negative tests for other toxic alcohols may be a diagnostic clue. Management is supportive care.

PUB215

Topiramate Causing a Mixed Renal Tubular Acidosis: A Case Report

Kadambari Jangam, Thomas R. Powell. *UPMC McKeesport, McKeesport, PA.*

Introduction: Topiramate is an anti-seizure medication that gained popularity in use for migraine prophylaxis. We report a case of hyperchloremic non-anion gap metabolic acidosis in a patient on Topiramate for migraine prophylaxis for. With its growing utility it is crucial to be cognizant of it's adverse reactions for prompt management.

Case Description: A 43-year-old female with a medical history of CAD, CKD 3b secondary to HTN, COPD, and migraine headaches presented with progressive confusion of 3 days witnessed by family. She was hemodynamically stable but had expressive aphasia on neurological exam. CT head without contrast showed no acute process. UDS was negative, acetaminophen, salicylate level, and ethanol levels were unremarkable. pH: 7.27/CO2:42/HCO3:19 on VBG. Serum Na: 147/Cl:121/K+:4/HCO3:22/Cr:1.4(at baseline)/BUN:32. UA: no proteinuria, nitrites, leukocyte esterase, or blood. Urine Na:131/Ur Cl:147/Ur K:34.6/Ur Cr:109.7/Ur pH:6.0/Ur anion gap:18.6/Ur osmolal gap:345. CPK:71. D5W with 100mEq of sodium bicarbonate at 100cc/hr was initiated. Her mentation returned to baseline with follow-up VBG:7.22/49/20, hypernatremia resolved. Respiratory acidosis was due to underlying COPD and NAGMA due to RTA from topiramate use(100mg daily for migraine prophylaxis). The patient was discharged home on oral sodium bicarbonate supplements with a plan to discontinue topiramate outpatient after discussuion with neurology.

Discussion: Topiramate is known to cause RTA by inhibition of carbonic anhydraze in both proxomal and distal tubule. Once a NAGMA has been established, urine pH, urine bicarb excretion, urine anion gap/osmolal gap, urine citrate, and beta-2 microglobulin can be used to differentiate between Type 1 and Type 2 RTA in the absence of GI loss. Type 1 has urine pH >5.5, urine Na>25 mEq/L, low urine ammonium, and citrate excretion. Type 2 has urine pH <5.3, increase urinary HCO3 and beta 2 microglobulin excretion. Our patient had urinary studies showing mixed RTA with increased urinary pH, low ammonia excretion (positive anion gap), and no concern for Fanconi syndrome(seen with type 2). Metabolic acidosis may lead to hyperventilation, altered mentation, nausea, vomiting, nephrolithiasis, and osteoporosis. Checking serum bicarbonate levels before initiation and at regular intervals in patients on the medication can help prompt management. Adequate hydration and alkali therapy is the mainstay of treatment.

PUB216

Slow Supratherapeutic Tylenol: A Recipe for Acidosis

Feruza Abraamyan,[1] Arrsh Bajaj,[1] Hilmer O. Negrete.[1,2] *[1]Mercy Health St Elizabeth Youngstown Hospital, Youngstown, OH; [2]Northeast Ohio Medical University, Rootstown, OH.*

Introduction: Acute acetaminophen (APAP) toxicity is the most common cause of liver transplantation in the US. However, its chronic ingestion can lead to depletion of the glutathione cycle, accumulation of 5-oxoproline (pyroglutamic acid), and development of severe high anion metabolic acidosis (HAGMA). Here we describe a case of a young woman admitted with severe persistent metabolic acidosis that required kidney replacement therapy after prolonged consumption of APAP.

Case Description: Briefly, a 37 y.o. female with a history of type II diabetes, heart failure, and recent left trans-metatarsal amputation due to gangrene was admitted due to shortness of breath and altered mental status. Her medications included metformin, spironolactone, sacubitril-valsartan, and hydrocodone-APAP. Her initial bicarbonate level was only 3 mEq/L, and her arterial pH was 7.01, BUN 17 mg/dL, creatinine 1.5 mg/dL, glucose 307 mg/dL, Na 129 mEq/L, K 5.6 mEq/L, Cl 101 mEq/L, Albumin 3.4 g/dL, anion gap 25 mmol/L (corrected 26.5), serum osmolality 305 mOsm/kg, alkaline phosphatase 249 U/L, ALT 70 U/L, AST 65 U/L. The beta-hydroxybutyrate level was only 0.32 mmol/L, and lactic acid 5.8 mmol/L. Urinalysis had no ketones, urine pH 5, and urine drug screen was negative. She was intubated and admitted to the intensive care unit. She was started on a bicarbonate drip and broad-spectrum antibiotics. Due to persistent acidosis, prolonged intermittent kidney replacement therapy (PIKRT) for 6 hours was started, followed by continuous kidney replacement therapy (CKRT). Sent-out tests were obtained: blood for metformin level showed a therapeutic range of 1.7 mcg/mL, and urine for pyroglutamic acid showed markedly increased excretion. Further history review with her husband revealed that the patient had been taking 3-4 tablets of APAP every 4-6 hours for the past 3 weeks for pain. The patient was diagnosed with severe HAGMA due to acquired pyroglutamic acidosis in the setting of chronic APAP toxicity. Eventually, she had adequate resolution of acidosis and was discharged to a long-term acute care facility.

Discussion: Pyroglutamic acidosis is under-recognized and can be a fatal cause of severe high anion gap metabolic acidosis. High clinical suspicion in the setting of risk factors and early recognition are paramount in improving outcomes. CKRT was beneficial in this situation to improve acidosis in the critical care setting.

PUB217

Symptomatic Uremia Without Significant Azotemia

Taylor R. Moody, Abutaleb A. Ejaz. *University of Maryland Medical System, Baltimore, MD.*

Introduction: Uremia is a clinical syndrome encompassing many non-specific symptoms such as anorexia, nausea, and fatigue. Typically, uremia occurs once the glomerular filtration rate (GFR) dips below 50% of average normal GFR, and overt uremia is not usually observed in patients with GFR greater than 10 ml/min and BUN lower than 100 mg/dL. In addition, the BUN represents one of many organic waste products that accumulate with decline in GFR and does not appear to contribute much to the uremic illness.

Case Description: A 61-year-old woman with CKD stage 3b secondary to diabetic nephropathy presented to the emergency department from nephrology clinic for acute kidney injury. Over the past year she had been losing weight due to intractable nausea, vomiting, diarrhea, and decreased appetite. During this time, she was at CKD stage 3b with blood urea nitrogen (BUN) ranging 28-39 mg/dL. Due to hyperbilirubinemia and elevated transaminases, she underwent extensive GI workup including gastric emptying study, abdominal CT and MRI, EGD, and liver biopsy. She was diagnosed with gastritis due to Helicobacter pylori infection which was treated without resolution of her symptoms. The liver biopsy showed hepatic steatosis and congestive hepatopathy. Nephrology was consulted and, though the BUN was only mildly elevated with a peak of 53 mg/dL, the patient was started on inpatient hemodialysis (HD) with marked improvement in her symptoms. After her second day of HD, she ate an entire personal pizza with no emesis when two days prior there were discussions regarding whether she should be started on total parenteral nutrition due to her prolonged anorexia and significant malnutrition.

Discussion: Uremia represents a constellation of symptoms related to accumulation of organic waste products as the GFR falls. The often-subjective nature of the diagnosis of uremia poses a great diagnostic challenge in patients such as this with rather unremarkable BUN levels. Diagnosis of uremia in the absence of significant azotemia represents an important gap in the extant literature because patients with symptoms impacting their overall quality of life would benefit from earlier initiation of renal replacement therapy (RRT) and may be spared expensive and invasive testing as a result. This case is an excellent reminder not to anchor on the BUN level when considering whether a patient has overt uremia requiring initiation of RRT.

PUB218

Drug-Induced Fanconi Syndrome with Hyperphosphatemia

Navneet Kaur, Muhammad W. Bajwa. *North Alabama Medical Center, Florence, AL.*

Introduction: Fanconi syndrome is characterised by proximal renal tubular dysfunction leading to hypophosphatemia, hypokalemia, hyperchloremic metabolic acidosis, glycosuria, and aminoaciduria. It is usually an inherited condition diagnosed in children, but can be acquired in adults as well, commonly due to drugs such as antimicrobials, antivirals, anticancer drugs, and valproate.

Case Description: An 81-year-old male presented from a nursing home with complaints of severe generalized weakness, and was found to have significant volume depletion, along with a potassium of 1.7, metabolic acidosis, acute kidney injury, and rhabdomyolysis. During the hospitalization, despite aggressive supplementation, he continued to have severe refractory hypokalemia and hyperchloremic metabolic acidosis. However, interestingly, the patient initially had hyperphosphatemia. Urine studies revealed glycosuria, proteinuria, and inappropriate sodium, potassium and phosphate wasting with increased fractional excretion of these electrolytes. After extensive work up ruled out other causes of these metabolic derangements, the leading differential was Fanconi syndrome. The patient had been recently started on valproate for bipolar disorder which is a known cause of Fanconi syndrome. However, one of the defining features of Fanconi syndrome is hypophosphatemia, whereas our patient had hyperphosphatemia. This was likely secondary to rhabdomyolysis, which might have been caused either by hypokalemia itself or prolonged immobility due to hypokalemia induced weakness. Another possible contributor was transcellular phosphate shift secondary to Fanconi syndrome induced metabolic acidosis. The patient's valproate was held and all electrolyte levels started improving. As expected in Fanconi syndrome, the initial hyperphosphatemia transitioned towards hypophosphatemia as the rhabdomyolysis and metabolic acidosis improved, and eventually normalized.

Discussion: Patients with Fanconi syndrome may have incongruous lab findings due to other causes, such as our patient with hyperphosphatemia due to rhabdomyolysis despite increased urinary phosphate excretion. It is thus important to critically examine every part of the clinical picture, in order to avoid erroneously ruling out the diagnosis. Urinalysis and electrolytes should be regularly checked in patients on valproate therapy as it is a known cause of Fanconi syndrome.

PUB219

Idiopathic Recurrent Serositis After Bilateral Nephrectomy in ADPKD

Neil S. Umles,[1] Joel M. Topf,[1,2] Heather L. Henderson,[1] Keith A. Bellovich.[1] *[1]Ascension St John Hospital, Detroit, MI; [2]Oakland University William Beaumont School of Medicine, Rochester, MI.*

Introduction: Nephrectomy in autosomal dominant polycystic kidney disease (ADPKD) is performed in up to 40% of patients being evaluated for renal transplant. Indications are recurrent or hemorrhagic cysts, urinary tract infections, large size of native kidneys or intractable pain. The most common complications are blood loss, iatrogenic bowel injury, and death due to sepsis. Few case reports have described recurrent ascites as a postoperative complication, usually of hepatic origin. This case describes recurrent serositis following bilateral nephrectomy with no apparent liver pathology.

Case Description: GP is a 72-year-old male with advanced CKD due to ADPKD. He underwent bilateral nephrectomy prior to a living unrelated donor transplant with hemodialysis planned as a bridge. In March 2022, he had open bilateral nephrectomy complicated by a liver laceration. Coagulation and liver function tests remained normal. He returned to the hospital 2 months later with complaints of worsening abdominal distention. CT showed new large bilateral pleural effusions, a pericardial effusion, and ascites. The pericardial effusion was drained, and pericardial biopsy showed no histologic abnormality or evidence of malignancy. Pleural fluid was transudative. Cytology and cultures were unremarkable. Initial ascitic fluid was indicative of portal hypertension, yet several repeats were not suggestive of portal hypertension. He was evaluated for tuberculosis, hepatitis B and C, lupus, and scleroderma, all of which were negative. An echocardiogram showed a newly reduced ejection fraction 30-35%, which recovered after CABG in June 2022. Transjugular liver biopsy in December 2022 was negative for cirrhosis or portal hypertension. He required biweekly paracentesis with removal of 6-8 L until the fluid tapered and resolved by January 2023. In February 2023 he received a deceased donor renal transplant. At 3 month follow up creatinine was 0.97 mg/dL with no further serositis.

Discussion: Bilateral nephrectomy for ADPKD has rarely been associated with recurrent ascites. Iatrogenic chylous ascites and ascites due to hepatic venous outflow obstruction or polycystic liver disease have been described. Neither non-iatrogenic pleural nor pericardial effusions following nephrectomy in ADPKD were seen on literature review. This case highlights serositis after nephrectomy, a yet undefined complication.

PUB220

Gitelman Syndrome: A 12-Year Diagnostic Challenge

Oluwadamilola Adisa, Ramanakumar Anam, Phani P. Morisetti. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Gitelman syndrome (GS), also known as familial hypomagnesemia-hypokalemia is an inherited salt-losing tubulopathy characterized by hypokalemic metabolic alkalosis with hypomagnesemia and hypocalciuria. Mutations in SLC12A3 gene is the underlying cause which results in defects in the apical sodium chloride cotransporter also known as the thiazide sensitive cotransporter in the distal convoluted tubule. GS is rare and inherited in autosomal recessive fashion with an estimated incidence of 1 in 40,000.

Case Description: We present a 26-year-old woman referred to the nephrology clinic for evaluation of chronic hypokalemia. It was first noticed at the age of 14, she reported several hospital admissions requiring treatment for hypokalemia. She was once admitted to the ICU after developing temporary paralysis which resolved with K+ replacement. She was subsequently prescribed 40mEq b.i.d of KCL. Her previous lab work showed K in range of 2.5-3 mmol/L and metabolic alkalosis. She denied any cramps, palpitations, weakness, polydipsia, salt cravings, vomiting, use of laxatives or diuretics. She reported taking OTC Mg supplements daily. Clinical examination was unremarkable. Her weight was 50kg with BMI 17.9 and BP was 116/79. Lab work showed aldosterone 24.7ng/dL and renin 14 ng/mL/h with a normal ARR of 1.76, other labs are shown in Table.1. She was counseled on likely diagnosis and informed consent was obtained to perform genetic testing which confirmed GS.

Discussion: The criteria for suspecting diagnosis of GS include; chronic hypokalemia with inappropriate renal K wasting (FeK > 9%); Metabolic alkalosis; Hypomagnesemia with inappropriate renal Mg wasting (FeMg > 4%); Hypocalciuria (spot urine Ca:Cr < 0.07mg/mg) 0.05mg/mg in this patient; High plasma renin activity (normal levels 0.6 – 4.3ng/mL/h); Fractional excretion of Cl > 0.5%; Low or normal-low BP and normal renal US. Clinical diagnosis can be challenging due to substantial number of mimics. Demonstrating biallelic mutations in SLC12A3 achieves a molecular genetic diagnosis of GS.

Table.1

Electrolyte	Serum value (unit)	Urine value (unit)	Fractional Excretion (FeX)
Potassium (K)	3.9 mmol/L	35 mmol/L	14.6%
Bicarbonate (HCO3)	25 mmol/L		
Magnesium (Mg)	1.6 mg/dL	5.74 mg/dL	5.8%
Calcium (Ca)	9.8 mg/dL	2.2 mg/dL	
Chloride (Cl)	104 mmol/L	82 mmol/L	1.3%
Creatinine (Cr)	0.7 mg/dL	43 mg/dL	

PUB221

Importance of Genetic Testing in APO L1 Nephropathy

Ananthalaxmi Vangapalli,[1] Sudhindra Pydimarri,[1] Madhurima Kunju,[2] Fareeha Mubin,[1] Astha Gupta,[1] Manjula Balasubramanian.[1] *[1]Albert Einstein Medical Center, Philadelphia, PA; [2]Lugans'kij derzhavnij medichnij universitet, Lugansk, Ukraine.*

Introduction: A 28-year-old non-diabetic, non-hypertensive female from West Africa (Mali) with pertinent history of pulmonary embolism, latent TB, recently diagnosed with H pylori on triple therapy, came to nephrology office for evaluation of proteinuria. Pertinent family history of ESRD on dialysis in 2 first degree relatives. No h/o smoking or alcohol use. Physical exam grossly normal.

Case Description: Initial labs showed creatinine 1 mg/dl, GFR 58. UA 1+ protein. UPCR of 2.3 g. Renal ultrasound showed increased echogenicity, normal size and cortical thickness. Serological work up for proteinuria including hepatitis B/C, HIV, ANA, SPEP

and UPEP was negative. Renal biopsy was performed for proteinuria. Pathology showed FSGS. Genetic testing was performed remarkable for homozygous APOL1 gene. She was CKD stage 3b/4 at the time of diagnosis of APOL1 nephropathy. Then progressed to ESRD now on hemodialysis.

Discussion: In 2010, genetic variants were discovered in the apolipoprotein L1 [APOL1] gene that explained a surprisingly large fraction of this major health disparity. Understanding the biology of APOL1 gene risk variance has been advancing at a molecular level [1] [2]. APOL1 gene is 1 of the 6 members of the APOL gene family on human chromosome 22. It is a naturally occurring gene that can be found in many organs of the body, including the podocytes of the kidneys [1]. Approximately 13% of African-Americans carry two APOL1 risk alleles. These variants termed G1 and G2, are a frequent cause of kidney disease-termed APOL1 nephropathy [2]. Spectrum of APO L1 nephropathy include HIV associated nephropathy [HIVAN], primary focal segmental glomerulosclerosis (FSGS), Lupus collapsing glomerulopathy, sickle cell disease nephropathy, and hypertension-attributed arterionephrosclerosis [6]. KDIGO 2021 guidelines for the management of glomerular diseases updated classification of FSGS into 4 types. One of them is genetic cause which includes APOL1 nephropathy leading to ESRD [3]. APO L1 kidney disease tends to be progressive, and current standard therapies are generally ineffective [2]. Multiple studies have demonstrated that APOL1 high risk donor kidneys fail at higher rates than non-risk kidneys, whereas the recipient APOL1 genotype has not yet been shown to affect graft survival [1].

Genetic Testing in Hemodialysis Patients

Kiran Munir, Steven Fishbane, Kenar D. Jhaveri, Daniel W. Ross. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: There is currently little available knowledge on potentially pathogenic genes present in patients on dialysis. The purpose of this study is to describe the prevalence of positive findings as well as variants of undetermined significance in an actively treated hemodialysis patient population.

Methods: At a large suburban academic medical center dialysis unit, patients were consented for genetic testing during dialysis treatment. Massive parallel genetic sequencing was performed using a panel of 385 genes with testing through Renasight platform via Natera Inc.(Austin, Texas, USA) (TM). Clinical parameters, demographics and vintage on dialysis were collected. Clinical care was not impacted for any patient regardless of their decision to participate.

Results: 75 of the 122 HD patients consented to enrollment. Genetic testing results were received for 71 patients. At the time of this analysis, four patients' results are pending. 66 identified as non- Hispanic while 9 identified as Hispanic. 31 patients identified themselves as white, 21 as African American, 14 as Asian and 10 chose not to report. Results are summarized in Table 1. 11 (15.5%) patients were found to have a gene allele meeting criteria to cause kidney disease. 27 (38%) patients were found to be carriers of autosomal recessive gene alleles known to cause kidney disease. 32 (45%) patients were found to have genes of unknown significance only. We were especially interested in APOL1 risk gene alleles. Of the 11 patients found to have a kidney disease causing gene allele, 6 patients were found to be positive for APOL1. 3 patients were heterozygous for the APOL1 gene but had 2 allele copies, and 3 were homozygous positive.

Conclusions: In an academic suburban center HD unit, 15.5% of HD patients were positive for disease causing genes and 45% of the patients have variance of unknown significance genes. Further studies will be needed to better understand the genetic disease prevalence and relevance in the ESKD population.

Category	Number of Patients
Patients consented	75
Patients with testing results	71
Patients with at least one gene identified	70 (98.6%)
Positive pathogenic genes causing kidney disease	11 (15.5%)
Carrier of pathogenic genes only	27 (38%)
Variance of unknown significance	32 (45%)

PUB223

Genetic Analysis and Minigene Splicing Assay of a New Splicing Variant of the COL4A5 Gene Causing Alport Syndrome

Jianrong Zhao. *Department of Nephrology, Affiliated Hospital of Inner Mongolia Medical University, Hohhot, China.*

Background: The aim of this study is to examine the genetic characteristics of a patient with Alport syndrome (AS) and confirm the existence of splice variant.

Methods: The study focused on a patient with AS who received a diagnosis at the Department of Nephrology of the affiliated Hospital of Inner Mongolia Medical University. Whole exome sequencing and Sanger sequencing were performed to identify gene variation sites. Additionally, mRNA abnormal splicing was conducted to investigate the impact of the variation on transcripts. 3D structure of the variant protein was analyzed. Immunofluorescence and immunohistochemistry were performed on the renal tissues of the patient to confirm the presence of AS kidney injury.

Results: Gene sequencing revealed that the patient had a splice variant c.835-9T>A in the *COL4A5* gene, which was not observed in either of the patient's parents. The experiment conducted in vitro revealed that the mutation c.835-9T>A (p.279_297del) resulted in the deletion of 57bp in exon 15 of the *COL4A5* gene mRNA. This deletion caused the loss of amino acid residues from positions 279 to 297, which in turn, impacted the stability of the secondary structure of the α5 chain encoded by the *COL4A5* gene. These amino acids are conserved across various species and their damage can be observed through evolution. The results of homology modeling indicated that the trimerization of Col-IV with the mutated α5 chain could be achieved, however, the 3D structure was found to be severely distorted. The diagnosis of AS kidney damage was confirmed through immunofluorescence results. Following the variant rating guidelines of the American Society for Medical Genetics and Genomics, c.835-9T>A was rated as a probable pathogenic variant (PVS1_Moderate+PS3_Moderate+PM2_Supporting+PS2+PP3+PP4).

Conclusions: The c.835-9T>A mutation in the *COL4A5* gene has been identified as the cause of disease in AS patients. In vitro experiments have confirmed that this mutation leads to splicing variation. Additionally, histopathological examination of the kidneys has provided in vivo evidence for the pathogenicity of the mutation and has expanded the spectrum of mutations associated with the *COL4A5* gene.

PUB224

Glomerulopathy with Fibronectin Deposits Caused by an FN1 Mutation in a Large Family with Variable Clinical Presentation

Federico Yandian,[1] Lucia Spangenberg,[3] Víctor E. Raggio,[2] Maria F. Dominguez,[2] Nicolas Delloca,[2] Lucia Facal,[1] Jessica M. Segarra,[1] Oscar A. Noboa,[1] Jose Boggia.[1] *[1]Department of Nephrology, Hospital de Clínicas "Dr. Manuel Quintela", Montevideo, Uruguay; [2]Department of Genetics, Facultad de Medicina, Universidad de la República, Montevideo, Uruguay; [3]Institut Pasteur de Montevideo, Montevideo, Uruguay.*

Introduction: Glomerulopathy with fibronectin deposits is a rare hereditary kidney disease with autosomal dominant inheritance. Mutations in the FN1 gene encoding fibronectin have been identified as responsible and account for 40% of cases. Light microcopy findings are non-specific. Electron microscopy shows: subendothelial and mesangial electron dense deposits with a granular or fibril-like structure.

Case Description: We describe a family with a diagnosis of focal and segmental glomerulosclerosis (FSGS) in whom the genetic test was crucial for a correct etiological diagnosis. The index case was a 46-year-old female with FSGS. Her mother had chronic kidney disease (CKD) with proteinuria and microhematuria as well as two maternal aunts (one deceased and the other one with FSGS on hemodialysis since 37 years old). Her deceased maternal uncle started hemodialysis at 42 years old, she also had a dead brother with FSGS who was a kidney transplant recipient, two maternal male cousins with CKD (one dead with kidney allograft) and two maternal female cousins with CKD (one of them with advanced CKD). The index patient received prednisone for 6 months and developed adverse effects. Interestingly, the patient and relatives had traumatological complaints,

but with unremarkable neurologic findings. Electron microscopy was not available. We performed a massive parallel sequencing for 70 genes known to be associated with FSGS and detected a heterozygous *FN1* mutation: NM_212482:exon8:c.A1123G, p.(Thr375Ala) which segregated with the disease. This information motivated the performance of a kidney biopsy in one of the female cousins who presented with proteinuria 0.73 g/day and normal creatinine clearance. It showed absence of hypercellularity and discrete mesangial matrix expansion. Immunohistochemistry revealed mesangial and pericapillary fibronectin staining. Electron microscopy: 70% foot process effacement and mesangial and subendothelial electron dense deposits, some with fibrillar substructure and others finely granular.

Discussion: Here we emphasize the importance of genetic testing when a familial renal disease is suspected, encouraging the use of non-standard histopathologic techniques for a correct diagnosis, like fibronectin immunohistochemistry stain in this case.

PUB225

Renal ANCA+ Vasculitis Concurrent with Fabry Nephropathy: Coincidence or Complication?

Michael L. West, Laurette Geldenhuys. *Dalhousie University, Halifax, NS, Canada*.

Introduction: Fabry disease (FD in an X-linked disorder of glycosphingolipid metabolism with chronic inflammation triggered by Gb3 and lysoGb3 metabolites. Various forms of glomerulonephritis (GN) and inflammatory disease have been reported with FD. Immune complex GN has complicated enzyme replacement therapy (ERT). GN including antineutrophilic cytoplasmic antibody (ANCA) disease has also been reported in association with COVID19 vaccination and infection. We report the case of a 73 year-old woman with type 1 diabetes mellitus, Fabry disease and COVID19 vaccination on ERT who presented with acute ANCA+ GN. Was Einstein right, there is no such thing as coincidence?

Case Description: The patient had stable diabetes since age 27, normal kidney function and low grade proteinuria 1 year prior. ERT (agalsidase alfa 0.2 mg/kg i.v. q2 wks) was given for 3 years for Fabry hypertrophic cardiomyopathy with moderate diastolic dysfunction. COVID19 vaccination was given 4 months prior to development of dyspnea, and acute kidney injury with microscopic hematuria. There was no extra-renal disease. Anti-myeloperoxidase (MPO) ANCA was positive. Renal biopsy showed focal proliferative GN with crescents plus background diabetic and Fabry nephropathies. She required hemodialysis. Despite treatment with glucocorticoids and Rituximab, there was no renal recovery. ANCA measurement in 83 FD adults revealed and negative results in 24M, 59F; transient false positive anti-PR3 ANCA occurred in 1M in which renal biopsy showed Fabry nephropathy plus an immune complex GN.

Discussion: FD has been previously reported with with renal vasculitis ANCA+ (antiPR3) in 1 patient and ANCA- in 2 patients. This is the first such case in which FD was already diagnosed and ERT given. ANCA associated vasculitis and other forms of GN usually occur within 90 days of COVID19 vaccination, mean 19 days, which does not fit with the observed time course in this case. The chronic inflammation of FD plus increased circulating MPO, the association with other GNs and other inflammatory conditions including vasculitis, the presence of kidney and lysosomal ANCA antigens, all suggest that vasculitis with or without ANCA is a rare complication of Fabry disease and Einstein was right. While our case did not improve with immunosuppressive therapy, others have, which suggests that FD patients should be treated for this serious but rare complication.

PUB226

A Decentralized Registry for Adults and Children with Alport Syndrome: Alport Syndrome Foundation (ASF) Alport Patient Registry Design

Lisa Bonebrake,[1] B. A. Weinstock,[1] Joshua Henderson,[2] Femida Gwadry-Sridhar.[2] [1]*Alport Syndrome Foundation, Phoenix, AZ;* [2]*Pulse Infoframe, London, ON, Canada*.

Background: The ASF Alport Patient Registry is a retrospective and prospective longitudinal, web-based, decentralized registry of patients of all ages with Alport syndrome (AS) in the USA. Genetic testing has become the primary means by which AS patients are correctly diagnosed in the USA. As such, newly diagnosed and engaged AS patients and their caregivers – as opposed to medical record repositories – are in a unique position to populate an up-to-date registry. The registry's primary objective is to collect real-world data to improve understanding of the natural history of AS; characterize kidney and non-kidney symptom presentation and diagnosis in patients; understand treatment practices and outcomes; and understand the quality of life and burden of disease. The registry also provides patient education resources and facilitates patient-centric research and therapeutic development.

Methods: Eligible patients of all ages with a verified clinical diagnosis of AS will be invited to participate. Diagnosis will be verified by a certified genetic counsellor or treating physician based on genetic test results -or- familial history, clinical signs, and kidney biopsy pathology if genetic results are inconclusive. Via web-based portals, patients or their caregivers will complete an initial survey and periodic follow-up surveys for as long as the participant chooses to be enrolled. Data collected are based on AS patient and clinical researcher inputs and include disease profile; medical, familial, and treatment histories - in particular RAASi and/or SGLT2i treatments; and genetic variant(s), audiological, and kidney laboratory results. Demographics and lifestyle characteristics are collected at enrolment and participant surveys are included at follow-up.

Results: Registry enrolment opened in May 2023. Data are anticipated for presentation in 2023.

Conclusions: The registry will be the first longitudinal registry in adult and pediatric AS patients collecting key determinants of patient management and outcomes, including the patient experience from diagnosis and treatment. The registry is positioned to become the primary US platform for real-world AS data that will facilitate education of patients and caregivers, inform clinical decision-making, and contribute to the development of therapeutic strategies with a better understanding of patient impact.

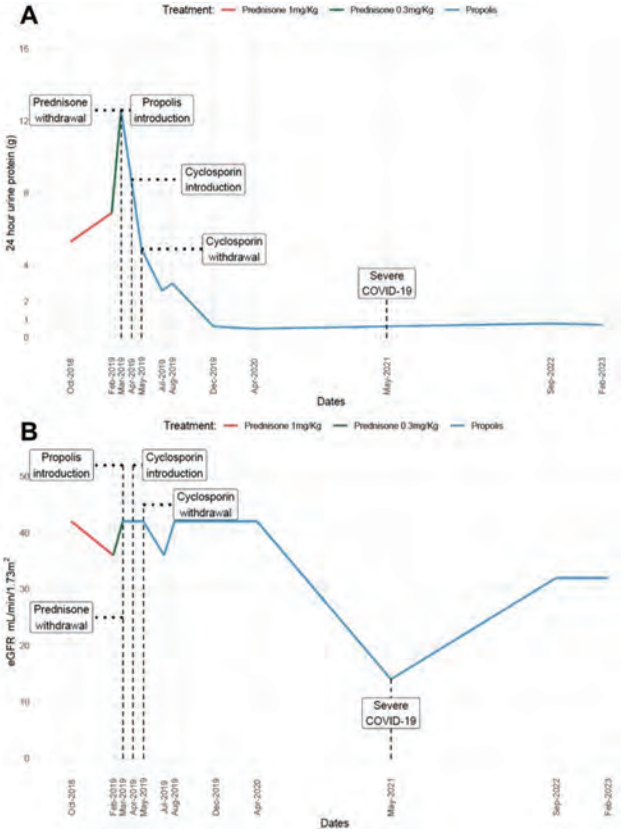
Collapsing Glomerulopathy (CG) in a Patient with High-Risk Apolipoprotein L1 (APOL1) Genotype: 4-Year Clinical Evolution of Use of Standardized Brazilian Green Propolis Extract (EPP-AF)

Marcelo D. Silveira, Sergio P. de Souza, Isadora G. Dultra, Ludmila B. Santos, Marcelo Lopes, Luis M. Conceição, Paulo benigno P. Batista, Rogerio Passos. *Hospital Sao Rafael, Salvador, Brazil*.

Introduction: Apolipoprotein L1 (APOL1) is expressed in podocytes and gene variants of high renal risk are associated with cell injury and glomerular damage. Collapsing glomerulopathy (CG) is one of the phenotypic expressions of these variants. Immune and inflammatory mechanisms may be related to its genesis, and specific treatments are not yet a reality. We hereby present data concerning the 4-year clinical evolution of a patient with APOL1 mutation of high renal risk in homozygosity and in use of standardized Brazilian green propolis extract (EPP-AF).

Case Description: A 41-year-old woman diagnosed with nephrotic syndrome in October, 2018, with proteinuria of 5.3 g/day at the time. Kidney biopsy revealed CG. The patient used prednisone 1 mg/kg for 12 weeks, showing no improvements and was found to have proteinuria of 12.6 g/day at the end of tapering in February, 2019. She did not tolerate ciclosporin. She has initiated the use of EPP-AF in March, 2019. Currently, four years later, the patient has proteinuria of 0.7 g/day. Glomerular filtration rate (GFR) was kept stable between 36-42 ml/min/1.73 m^2 for more than two years until the moment the patient had severe Covid-19 and GFR dropped and is currently at 32 ml/min/1.73m^2 .

Discussion: APOL1 mutation of high renal risk may be associated with CG with a poor prognosis. Covid-19 may be associated with more severe damages among these patients. Typical immunosuppression is oftentimes ineffective. The use of EPP-AF in this case was able to control nephrotic syndrome for four years.



PUB228

A 2-Year Analysis of Collagen IV Mutations in the Minho Region, Portugal

Sofia H. Marques, Maria Lopes-de-Almeida. *Hospital de Braga, Braga, Portugal*.

Background: Monogenic diseases represent 10-15% of chronic kidney diseases (CKD). More than 400 genes have been associated with hereditary nephropathies. However, genetic testing for kidney diseases remains scarce. Pathogenic mutations in COL4A3,

COL4A4 and COL4A5 may underlie different diseases such as isolated hematuria, Alport syndrome, diabetic kidney disease and focal segmental glomerulosclerosis (FSGS). In Portugal, there are regional diagnostic practices and patterns of genetic diseases. Our aim is to analyze the results of Braga Hospital concerning collagen IV mutations in the last 2 years.

Methods: We reviewed medical records and genetic test results of patients with variants in type IV collagen genes. A targeted panel covering 3 genes (COL4A3-5) using next generation sequencing (NGS) based on whole exome sequencing was applied. In certain cases, a larger panel covering genes implicated in FSGS was used.

Results: Approximately 1800 new patients attended our Nephrology department during 2021 and 2022. During this period, 62 patients underwent genetic testing to search for a hereditary cause of kidney diseases. In particular, 29 were tested for mutations in COL4A3-5 using the 3-gene (18 cases) or a larger FSGS NGS panel (11 cases). All patients were unrelated, 15 were women, mean age was 55±15 and 20 had a family history of CKD. Most were refered for CKD of unknown cause, microhematuria and proteinuria; 6 had hearing loss and 10 had a biopsy showing FSGS. Pathogenic variants were found in 4 patients and variants of uncertain significance (VOUS) in 5. The remainder had negative results. Of the 4 pathogenic mutations, all were heterozygous; 3 affected COL4A4 and the other COL4A3. These patients had a median creatinine of 1mg/dL (range 0.8 – 2.6mg/dL), median protein/creatinine urinary ratio of 1g/g (range 0.3-3.4g/g), 3 were women and 3 had kidney biopsies with FSGS. Of the 5 VOUS, 3 were in COL4A4, 1 in COL4A3 and 1 in COL4A5, in a female patient.

Conclusions: Despite probable underdiagnosis, genetic tests improved diagnostic accuracy even after renal biopsy. The clinical spectrum of heterozygous variants of COL4A3, COL4A4 or COL4A5 in female carriers varies: most likely they are disease modifiers for a range of kidney diseases, one of which, as occured in our series, is FSGS. Further research is needed to better understand their role in nephropathies other than Alport syndrome.

PUB229

Autosomal Dominant Tubulointerstitial Kidney Disease due to Uromodulin Mutation (ADTKD-UMOD)

Aarzoo Gupta, Anuroop Yekula, Susant O. Gurung, Ashish Verma. *Saint Vincent Hospital, Worcester, MA.*

Introduction: ADKTD-UMOD is a rare genetic disorder manifesting as a slowly progressive chronic kidney disease that usually leads to end-stage kidney disease (ESKD). Here we present a patient with a typical presentation of ADKTD-UMOD-related CKD.

Case Description: A 51-year-old white male with long-standing hypertension was evaluated a decade ago for slowly progressive CKD. He had 300-1000 mg/d proteinuria. Urine sediment was bland. Kidney imaging, hepatitis B & C titers, C3 & C4, ANA, SPEP, UPEP & IF were negative. CKD was attributed to hypertensive kidney disease and efforts were directed at suppressing proteinuria and keeping blood pressures consistently below 130/80 mmHg with ACEI/ARB. After relative stability for about 4 years, creatinine started to worsen rapidly. Sediment showed WBC casts and the patient mentioned he was taking a kidney health herbal supplement. This was stopped and a brief trial of steroids ensued with transient improvement of creatinine only to relapse a few months later. The above workup was repeated and was negative but a kidney biopsy showed tubulointerstitial nephritis besides with secondary adaptive FSGS, over 50% globally sclerosed glomeruli, and over 60% cortical atrophy with advanced arterial and arteriolar hyalinosis. A repeat course of steroids made no difference and was rapidly tapered off. A renal genetic panel was performed, and the patient tested positive for UMOD gene variant c.317 G>T which is known to be associated with ADTKD-UMOD. The patient was provided genetic counseling for the self and at-risk family. He is currently under evaluation for home dialysis and kidney transplantation.

Discussion: Uromodulin (UMOD), also known as Tamm-Horsfall protein is exclusively produced in the kidney. It regulates salt transport and protects against urinary tract infections, stones, and immune-mediated insults. Approximately 1% of patients with CKD stages 3–5 have UMOD gene mutations. ADTKD-UMOD is considered rare and mostly remains unrecognized due to the paucity of genetic testing. The disease is often insidious without characteristic hematuria or proteinuria. As no treatment options are as yet available for halting disease progression, dialysis and transplantation are often the primary therapy modalities. Full genome analysis might be helpful in identifying the etiology of CKD, prognostication, and family counseling.

PUB230

A Peculiar Case of Hypercalcemia

Aarzoo Gupta, Anuroop Yekula, Felipe Fernandez del Castillo. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Hypercalcemia is common in adults and typically results from increased calcium and Vitamin D intake or from hyperparathyroidism. With the increased feasibility of genetic testing, various underlying gene defects have surfaced in previously idiopathic hypercalcemic cases. Here we present a scenario of a rare genetic cause for persistent hypercalcemia, complicated by recurrent kidney stones.

Case Description: A 23-year-old male with a history of hypertension presented with gross hematuria. Abdominal imaging revealed a 1 cm ureteral stone with bilateral medullary nephrocalcinosis. The retrieved stone fragments consisted of calcium oxalate. Metabolic testing showed hypercalcemia of 11 mg/dl, with low 25 OH D and PTH levels. Kidney function and other electrolytes were normal. A 24-hour urine collection revealed increased urinary calcium excretion of 260 mg/day and decreased urinary citrate of 236 mg/day. He was instructed to increase fluid intake, start potassium citrate supplements and adhere to his thiazide diuretic. In spite of adherence to these recommendations, he continued to have symptomatic nephrolithiasis, prompting additional workup. A SPEP with immunofixation, ACE levels, TB testing, and PTHrP were unremarkable. His 1,25 OH-D level was elevated at 90 pg/mL. Given a strong family history of nephrolithiasis, a comprehensive genetic analysis was sent demonstrating a homozygous loss-of-function defect in the CYP24A1 gene which has been previously reported as a cause of hypercalcemia.

Discussion: Genetic causes of hypercalcemia have been identified in recent years with the advent of clinically practical genetic testing. In our patient, a previously reported rare gene mutation of the CYP24A1 was noted as the source of hypercalcemia. CYP24A1 encodes the enzyme 24-hydroxylase, which is typically responsible for calcitriol breakdown. Homozygous inactivating mutations in this enzyme can cause PTH-independent hypercalcemia, hypercalciuria, and nephrolithiasis. Because the mechanism of hypercalcemia is from hypervitaminosis D due to deficiency of 24-hydroxylase, therapy should be directed at lowering vitamin D levels. Drugs like fluconazole inhibit the activity of 1-alpha hydroxylase and can be used to reduce active vitamin D levels, restoring normal calcium balance. Our patient was started on fluconazole 50 mg, with subsequent normalization of his serum calcium level and no further stone episodes.

PUB231

Extrarenal Manifestations of Atypical Hemolytic Uremic Syndrome: A Systematic Review and Meta-Analysis

Kush Doshi,[1] Abdel Rahem S. Yusuf,[2] Sidharth K. Sethi,[3] Olivia Boyer,[4] Carla M. Nester,[5] Pranjal Sharma,[2] Christoph Licht,[6] Rupesh Raina.[1,7]
[1]Cleveland Clinic Akron General, Akron, OH; [2]Northeast Ohio Medical University, Rootstown, OH; [3]Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India; [4]Structure Federative de Recherche Necker, Paris, France; [5]Departments of Internal Medicine and Pediatrics, Division of Nephrology, Carver College of Medicine, University of Iowa, Iowa City, IA; [6]The Hospital for Sick Children, Toronto, ON, Canada; [7]Akron Children's Hospital, Akron, OH.

Background: Atypical Hemolytic Uremic Syndrome (aHUS) is a chronic thrombotic microangiopathy (TMA) resulting from abnormal alternative complement pathway activation. Although renal vasculature is commonly targeted, aHUS can involve many organ systems. Our review investigates the incidence and clinical outcomes of aHUS patients with extrarenal manifestations.

Methods: The literature search was conducted through PubMed/Medline, Embase, Web of Science Core Collection, and CINAHL. The search criteria comprised terms such as 'aHUS', 'extrarenal', and various individual organ systems. Clinical features specific to the patient were collected, including extrarenal involvement, laboratory values, genetic abnormalities, and adverse outcomes. The meta-analysis was completed using SPSS version 22.

Results: In total, 47 studies were included encompassing a sample size of 890 aHUS patients. The most widely reported genetic abnormalities were in factor H (CFH) mutations [12% (84/700 patients); n=19 studies] and anti-FH IgG antibodies [27.1% (102/376 patients); n=10 studies]. The most commonly occurring extrarenal manifestations across the included studies were related to the central nervous system [28% (240/858 patients), n=32 studies], with seizure being the most-common CNS symptom. This was followed by the gastrointestinal system [31% (230/741 patients); n=25 studies] and the cardiovascular system [16% (97/607); n=23]. The proportion of aHUS patients with end-stage renal disease was reported across 11 studies in 13.2% (61/463 patients) of this subpopulation, and the mortality rate was 8.9% (56/632 patients) across 27 studies.

Conclusions: Extrarenal manifestations were present in approximately 20-30% of aHUS patients, depending on age and organ system. Our findings indicate neurologic and gastrointestinal involvement to be the most incident. Studies infrequently report genetic findings and are limited in population size, warranting larger multi-centered cohort investigations.

PUB232

Hereditary Renal Amyloid and Kidney Transplantation

Sadia Jahan, Jenny Latte. *Central and Northern Renal and Transplantation Service, Adelaide, SA, Australia.*

Introduction: Lysozyme amyloid is a rare cause of end stage kidney disease which can present with a wide range of symptoms. We present a patient with this genetic condition with a positive family history, who has since undergone a successful transplant.

Case Description: Our patient presented at the age of 63 to the renal outpatient department with elevated creatinine; 185umol/L and a urine albumin-creatinine-ratio of 3.7mg/mmol after routine testing. She did not have a history of diabetes or hypertension. It was known that her son had the diagnosis of lysozyme amyloid, and she underwent genetic testing, along with a renal biopsy. The biopsy showed renal amyloidosis with deposits largely restricted to the interstitium and artery/arterioles. The glomeruli were preserved explaining her low proteinuria despite amyloid deposition. Within 3 years she had progressive kidney failure requiring consideration of kidney replacement therapy. During transplant work up, she had a positive faecal occult blood testing and colonoscopy showed gut mucosal involvement of amyloid with numerous irregular round eosinophilic acellular nodules in the lamina propria, also positive on the Congo red stain. There was no cardiac involvement. With careful consideration, she underwent a directed living transplant, at 3.5 years post diagnosis of this condition. 2 years post transplantation, our patient's graft has BK nephropathy, but of note, biopsy has not shown recurrence of amyloid deposition.

Discussion: Our patient's genetic test returned positive for variant LYZ:c.314A>T. Lysozyme is an amyloidogenic precursor protein and in lysozyme amyloid, it is a ubiquitous bacteriolytic enzyme synthesized by hepatocytes, polymorphs, and macrophages. Currently, there is no amyloid-specific therapy apart from supportive management. The National Amyloidosis Centre in UK published a case series of three patients who underwent kidney transplantation, and there was no recurrence at the time of publication (0.8, 1.8 and 6.6 years post transplantation). Our patient's type of amyloid is different to AA, AL amyloid where recurrence might be expected. There may be a role for genomic sequencing for patients with amyloid deposition in biopsy, with no notable family history, which may lead to identification of rare amyloid types.

PUB233

Using Ambulatory Genetic Testing to Improve the Evaluation of Kidney Diseases in Our Veterans

Zachary Kornblum,[1,2] Christopher D. Naranjo,[1,2] Mary Sifain,[1,2] Chavely Valdes Sanchez,[1,2] Margarita D. Almeida,[1,2] Marco A. Ladino Avellaneda.[1,2] University of Miami/Miami VAMC Fellowship Program. *[1]University of Miami School of Medicine, Miami, FL; [2]Miami VAMC, Miami, FL.*

Background: Chronic kidney disease (CKD) is a major public health issue in the United States, and also for our veterans. Monogenic causes are present in ~10% of cases of adult CKD. Identification of causes of CKD can impact prognosis and patient management. In our Nephrology clinic at the Miami VAMC, we evaluate patients with chronic kidney disease (CKD), and occasionally no clear etiology of CKD is identified. Broad genetic panels can provide an unbiased testing approach, which is advantageous in phenotypically heterogeneous diseases. However, the use and yield of broad genetic panels by VA Nephrologists in clinical practice is not yet well characterized.

Methods: A total of eight patients were selected to have renal genetic testing. Seven patients had unclear causes for kidney disease, and one patient had a questionable genetic condition on imaging studies. Renal genetic testing was performed in 8 patients. Genetic testing was executed using Renasight and Fulgent, commercially available sequence-based tests for 385 genes associated with kidney disease. Renasight and Fulgent determine if there is a genetic cause for an individual's kidney disease, or if there is an increased hereditary risk due to family history. Results were available in 4 weeks.

Results: See image.

Conclusions: Use of broad panel genetic testing by our clinical Nephrologists had a high success rate in identifying etiologies of CKD in our veteran population. Establishing a genetic diagnosis is crucial to define the precise etiology of CKD. Accurate genetic testing allows improved genetic counselling and enhanced patient management. Implementation of various genomic strategies has resulted in a direct, demonstrable diagnostic and therapeutic benefit to affected patients.

Patient	Indications for Genetic Testing	Result
1	Hematuria, CKD unknown etiology	COL4A3 Heterozygous
2	Hematuria, CKD unknown etiology	Negative
3	Hematuria, CKD unknown etiology, CHF unknown etiology	APOL1 Heterozygous; Hereditary Transthyretin Amyloidosis (TTR) Heterozygous
4	CKD unknown etiology	Negative
5	CKD unknown etiology	RPGRIP1L carrier (Ciliopathy associated w/ Meckel/Joubert syndrome and COACH syndrome)
6	Kidney cyst evaluation, rule out PCKD	Negative
7	Elevated creatinine, unclear cause	Negative
8	Elevated creatinine, unclear cause	Negative

Autosomal Dominant Alport Syndrome in a 62-Year-Old Hispanic Woman: A Clinical Case Report

Jeanine Hernandez,[1] Mohamed G. Atta,[2] Celia P. Corona Villalobos,[1] Chirag R. Parikh,[2] Lois J. Arend,[2] Steven Menez.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Medicine, Baltimore, MD.*

Introduction: Alport syndrome (AS) is a monogenic disease caused by mutations in the COL4A3/4/5 genes encoding collagen IV, often characterized by progressive kidney function decline, hearing loss, and vision loss. It has an autosomal dominant inheritance pattern in approximately 5% of cases. Autosomal dominant Alport syndrome (ADAS) may be underdiagnosed due later onset of disease.

Case Description: We present a case of a 62-year-old Hispanic woman who presented for evaluation in nephrology clinic with bilateral renal cysts, chronic microscopic hematuria, proteinuria (5.13 g/g), and secondary hypertension. She stated that she had been experiencing arthritis, otalgia, and noted a history of LASIK eye surgery. IgA nephropathy and thin basement membrane disease were highest on the differential diagnosis. A kidney biopsy was performed showing thin glomerular basement membranes with an average width of 130 nm, and focal segmental glomerulosclerosis. However, given her significant proteinuria and subtle GBM changes concerning for a collagen defect, genetic testing using next generation sequencing was performed and revealed a heterozygous pathogenic variant, c.2794A>T (p.Lys932) in the COL4A4 gene that is associated with ADAS. Her baseline creatinine was 0.76 mg/dL, increased at the time of diagnosis to 0.9 mg/dL with a downward trend most recently stabilizing at 0.71 mg/dL. Evaluation by ophthalmology and audiology excluded ocular findings or hearing impairment. She was subsequently started on Losartan and dapagliflozin, with the goal to slow kidney disease progression and prevent end-stage kidney disease (ESKD).

Discussion: ADAS is characterized by a later age of onset and rare extra-renal manifestations in contrast to autosomal recessive disease. Next generation sequencing has increased the frequency of ADAS diagnosis compared to pedigree analysis and Sanger sequencing and should be considered in suspected patients regardless of age. ADAS carries >20% risk of ESKD highlighting the importance of early recognition and multidisciplinary management for improving outcomes in affected individuals.

PUB235

Mortality Risk Factors in Elderly Patients Undergoing Hemodialysis in a Nursing Home

Satoko Notomi,[1] Mineaki Kitamura,[2] Emiko Otsuka,[1] Satoshi Funakoshi.[1]

[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Harbor Medical Cente, Nagasaki, Japan.

Background: As patients undergoing hemodialysis (HD) advance in age, they often exhibit greater mental and physical frailty, resulting in an increased number of patients requiring nursing care. However, few studies have examined the risk factors contributing to mortality in this subpopulation. Our dialysis center is affiliated with a nursing home, and most residents are elderly patients undergoing HD. This setup enabled us to assess the nursing home residents during follow-ups in medical and nursing care aspects. We aimed to clarify the mortality risk factors in this subpopulation.

Methods: We included patients undergoing HD who were admitted to our affiliated nursing home between April 2014 and March 2022. Patients with dialysis duration of <3 months were excluded. All participants were followed up until March 2023 and their medical data were collected upon admission. The association between survival and patient demographics was analyzed.

Results: This study included 106 patients (81.3 ± 7.9 years old; 36.8% men; median dialysis vintage, 32.5 months). The most commonly reported cause of death was pneumonia (19.1%), followed by heart failure (16.0%) and infections (8.5%). The patients were stratified into two groups based on their body mass index (BMI), and Log-rank test analysis revealed a poorer prognosis for those with a lower BMI than those with a higher BMI (p=0.002). Multivariable Cox proportional hazards analysis demonstrated a significant association between BMI (hazard ratio, 0.87; 95% confidence interval [CI]: 0.82–0.94; p<0.001) and survival rate. Additionally, multivariable logistic regression indicated that dementia was significantly associated with a lower BMI (odds ratio: 2.89, 95% CI: 1.07–7.83, p=0.03).

Conclusions: Our findings revealed that low BMI is an important factor contributing to a lower survival rate. Furthermore, low BMI was also associated with dementia. Therefore, energy supplementation and management of dementia could be essential for nursing home residents undergoing HD to improve their survival rate.

PUB236

AKI in the Elderly: The Tip of an Iceberg

Lakshna Sankar, Pooja Sanghi. *Geisinger Health, Danville, PA.*

Introduction: Acute kidney injury (AKI) in the elderly is of multiple etiologies. Renal biopsy remains the gold standard for diagnosis.

Case Description: A 68-year-old male with history of rheumatoid arthritis on adalimumab was re-admitted with altered mental status, poor oral intake and AKI after a recent hospitalization for lumbar osteomyelitis requiring long term intravenous (IV) cefepime. Work up including infectious, autoimmune profile and renal imaging were unremarkable. Hemodialysis was contemplated due to worsening renal function with creatinine at 8.4 mg/dl (reference range: 0.5 - 1 mg/dl), hyperkalemia and concern for uremic encephalopathy, but he responded to supportive care with IV fluids and IV piperacillin tazobactam. A thorough history revealed intake of nabumetone for several years at doses as high as 1.5 gm daily. Renal biopsy was obtained due to unclear etiology of AKI in the setting of multiple confounding factors such as medications and recent infection. Biopsy showed features of acute interstitial nephritis (AIN) and few myoglobulin positive tubular casts of unclear significance (Figure 1). Antibiotics and nabumetone were discontinued. He was treated with steroids, had marked improvement in creatinine (Figure 2) and was discharged home with steroid taper over 6 weeks.

Discussion: Aging kidneys are more susceptible to AKI due to low renal reserves. AKI developed during hospitalization has high mortality. A thorough understanding of etiology, clinical course and having a low threshold for kidney biopsy aids in diagnosis of AKI with possibilities of better outcomes in the elderly population.

PUB237

Trajectory of Physical Function and Resilience in Incident Dialysis Patients

Samantha F. Smoger, Derek M. Devine, Katharine L. Cheung. *University of Vermont, Burlington, VT.*

Background: Initiating dialysis is a stressor and associated with functional decline. Resilience is a protective factor that may help patients starting dialysis. We aimed to describe the correlation between and trajectories of resilience and function in the first year of dialysis.

Methods: Incident dialysis patients ≥ 50 years were recruited from 2016-19. The short physical performance battery (SPPB) and Resilience Scale were performed at baseline and 1, 2, 4, 6, and 12 months. Age, sex, income, education, eGFR, serum albumin, cognitive status and comorbidities were identified from EMR and surveys. Spearman's correlation coefficient was used to assess the relationship between resilience and function. Multivariable linear regression was used to identify predictors of resilience and function. Mixed model analyses were used to determine resilience and function trends over 12 months.

Results: 58 incident dialysis patients participated, mean age 68 years, 43% female. At baseline, median (IQR) resilience was 152/175 (135-159) and SPPB was 5.5/12 (1-8). Correlation of resilience and function was ρ -0.23. Serum albumin was independently associated with SPPB; no variables were predictive of resilience. Trajectories of function and resilience are shown in the Figure.

Conclusions: Resilience and function are inversely correlated and decrease in both after 4 months then improve to baseline at 1 year. Greater study is needed to understand predictors of resilience and whether it might improve function for this population.

Trajectories of function and resilience

PUB238

Medication-Induced Acute Encephalopathy in Severely Impaired Renal Function

Reed Shank. *The Christ Hospital, Cincinnati, OH.*

Introduction: Commonly we as providers understand the importance of renally dosing certain medications or avoiding others altogether when we encounter a patient with impaired renal function. More commonly we will avoid modalities of diagnostic testing fearing we will further damage the already injured kidneys. However almost just as frequently we don't consider renal impairment when prescribing other common medications due to lack of education, experience or alternatively over confidence in our knowledge of the drug.

Case Description: The patient is a 76 year old man with a history significant for end stage renal disease (on peritoneal dialysis), coronary artery disease and diabetes who presented to the ICU with altered mental status. He was recently admitted to a different hospital 3 days ago for right sided facial numbness, pain and dysgeusia for which he was given gabapentin, Percocet and acyclovir as it was suspected trigeminal neuralgia. On day 5 of this previous admission he became acutely encephalopathic while the neurological workup including MRI returned negative. He was transferred to our ICU for further management. He was given Narcan numerous times without improvement nor did a round of peritoneal dialysis improve his mental status. Upon arrival family stated he was normally very interactive and appropriate. After 2 days of withholding opiates, gabapentin and acyclovir his mental status finally began to improve.

Discussion: Upon further review, we believed the offending medication to be acyclovir (1) and this was suspicion confirmed by the nephrologist on the case. It is rare but certainly can happen especially in the elderly (2). For many of us this was the first time hearing that acyclovir could be the offending agent. How could a medication so commonly prescribed without consideration of renal function be overlooked as the cause of acute encephalopathy? It is clearly important to have a deep understanding of what medications are renally excreted which is typically information covered in medical school but not necessarily reinforced in the primary care and hospital medicine settings. Additional education and appreciation of this concept would most likely result in safer treatment and shorter hospital stays. Had this been realized in the above patient, he would have not required a transfer nor a 2 day ICU stay costing the medical system both resources and space.

PUB239

Impact of Body Mass Index on Mortality of Elderlies Requiring Acute Hemodialysis

Alfredo Fonseca Chávez, Lillana Pacchiano, Marcos G. Nava, Ivan A. Osuna Padilla, Jose A. Leon, María Carolina R. Bolaños, Jesus Arturo R. Martinez. *Instituto Nacional de Enfermedades Respiratorias, Mexico, Mexico*.

Background: The increasing life expectancy of the world population elicited the increasing numbers of elderly patients starting hemodialysis (HD), however little is known about the impact on those requiring acute hemodialysis. Malnutrition is alredy related with a higher risk of mortality in non elderly HD patients. The purpose of this study is to evaluate these factors in the elderly population who requiere acute hemodialysis.

Methods: Retrospective cohort of 33 patients >70 years requiring Hemodialysis was categorized based on their Body Mass Index as normal (18.5-24.9 kg/m2), overweight (25-29.9 Kg/m2) and obesity (>30 kg/m2). Kaplan Meier survival analysis with log-rank test and the Cox proportional hazards model were performed to assess the association between BMI 120-day mortality. Multivariate regression analysis was performed to know the independent association with increased mortality.

Results: Differences in BMI were observed between survivors (15 patients) and non-survivors (18 patients) (p=0.02). Cox-Analysis shows a higher risk of mortality in normal BMI (HR 1.98, 95% CI 0.76-5.13, p value=0.15). A significant association was found between normal BMI and 120-day mortality (HR = 3.28,95% CI = 1.04 - 10.29;P value = 0.041).

Conclusions: A normal BMI was associated with higher risk of mortality in unplanned hemodialysis elderly patients.

External Validation of a Risk Prediction Tool in Determining Early Death Among Elderly Patients Initiated on Dialysis

Rachelle Zolla S. Ciudadano-Manalaysay, Trisha Michelle Manalaysay. *Southern Philippines Medical Center, Davao City, Philippines*.

Background: The increase in the senior population is one of the factors that has contributed to the rise in the number of dialysis patients in the Philippines. The elderly generally has an increased risk for poor dialysis-associated outcomes, and studies have been conflicting if they have better survival with dialysis as compared to conservative management. The Thamer Risk Scoring tool uses simple variables to predict early mortality in elderly patients after initiating dialysis, however this has not been validated in the Philippine setting.

Methods: A retrospective cohort research design was used. Patients ≥ 60 years old, diagnosed with end-stage renal disease, and initiated on dialysis from 2018 to 2021 in a tertiary institution in the Philippines were subjected to the tool to predict 3-month, 6-month, and over-all mortality after dialysis initiation. Patients with <90 days dialysis duration, recovery of kidney function, and with incomplete data to meet all the variables for the tool were excluded.

Results: Majority of the 181 patients included in the study were male (56.35%), and initiated on hemodialysis (97.24%). The mean age of the population was 67.34 years. All-cause mortality was 38.12% at 3 months, and 3.57% at 6 months after dialysis initiation. Patients with heart failure, cancer, asthma, and need for assistance in daily living had significantly higher mortality rates (p-values 0.007, 0.040, 0.040, 0.022 respectively). In comparison to the Thamer study with an AUROC = 0.691 for the tool in their validation cohort, this study showed an AUROC = 0.6245, 0.2847, and 0.5993 in the 3-month, 6-month, and over-all mortality groups respectively. As the score increased for the three groups, the tool became less sensitive and more specific with a concomitant increase in accuracy for predicting mortality.

Conclusions: Despite the poor performance of the Thamer risk scoring tool in predicting mortality in terms of AUROC in this study, the sensitivity, and specificity had a similar performance in the Thamer study. Furthermore, the consistent trend of accuracy of predicting mortality in these groups reflect that a higher score portends to a higher accuracy in predicting mortality.

PUB241

Kidney Biopsies in Elderly Patients: Analysis of a 7-Year Institutional Experience

Sebastian Consuegra-Flores,[1,2] Fernando A. Cuellar-Gonzalez,[1,2] Mauricio Arvizu Hernández,[1] Jorge I. Fonseca-Correa.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Tecnologico de Monterrey Campus Ciudad de Mexico, Mexico City, Mexico.*

Background: Kidney biopsies are essential for diagnosing and guiding treatment decisions, but limited data exist on their utility and safety in older adults (> 60 years). This study aims to analyze kidney biopsies performed on patients aged 60 years and above at our institution from 2015 to 2022, considering age-related changes, comorbidities, and survival influences.

Methods: A retrospective analysis of 78 kidney biopsies in elderly pts. was conducted. Demographic data, comorbidities, and pathological findings were collected to evaluate indications, procedural characteristics, and complications associated. All biopsies were performed by Nephrologists and Interventional Nephrology fellows.

Results: Among the 78 biopsies, 53 were performed on pts. aged 60-70 years, and 25 on pts. above 70 years (only 3 pts. aged ≥ 80 years). The mean pts. age was 68±7.1 years, 56% were female. The primary indication for biopsy was Nephrotic Syndrome (58.9%), followed by Acute Kidney Injury (9%). All patients met institutional protocol criteria prior to biopsy. The most common diagnoses were Pauciimmune Glomerulonephritis (19.2%), Diabetic Nephropathy (15.3%), Acute Interstitial Nephritis (12.8%), Focal Segmental Glomerulosclerosis (10.2%), Amyloidosis (10%) and Membranous Nephropathy (8.9%). Frequency needle passes were 1 in 34% and 2 in 55%. Minimal complications were observed, only 3 pts. with small hematomas, were monitored by ultrasound; no blood transfusions or interventions for bleeding were required and no major complications were observed.

Conclusions: Kidney biopsies in elderly pts. offer valuable diagnostic information and aid in tailoring management strategies. Nephrotic Syndrome was the leading indication, and Pauciimmune Glomerulonephritis was the most common diagnosis. Understanding the diagnostic yield, prevalent etiologies, and potential complications associated with kidney biopsies in the elderly is crucial for personalized care in this vulnerable population.

PUB242

Diagnostic Impact and Safety of Percutaneous Kidney Biopsy in Adults Older Than 65 Years

Karime Berenice R. Santos,[1] Brenda Cortez,[1] Omar H. Sanchez Vazquez,[2] Alejandro Garcia Rivera,[2] Bernardo Moguel.[1] Nephro.Mex. *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico.*

Background: Population older than 65 years has been increasing worldwide and the incidence of kidney disease. Currently, there are no consensus defining an age limit for percutaneous kidney biopsy (PKB). Some centers do not perform routinely this procedure in this population.

Methods: Retrospective cross sectional study spawning data from 2019-2022 of patients >65 years old that underwent a PKB at Interventional Nephrology Service of the National Institute of Cardiology "Dr. Ignacio Chávez". Sampling was performed in real time guided by ultrasound. We describe demographic data, comorbidities, kidney morphology and histological findings.

Results: 35 patients underwent a PKB were analyzed. 65.7% were women; the mean age was 71.8 years with a mean GFR of 50.2 ml/min/1.73 m2, and mean kidney length of 9.56 cm. 54.28% were performed as outpatients. Mean of needle passes was 1.6 and the mean number of glomeruli was 16.9. Complications occurred in 8 patients, 5 were minor (macroscopic hematuria or hematoma < 2cm), and just 3 were major (hematoma > 2cm). There was no need for blood transfusions, nephrectomies or deaths. The most frequent pathology diagnosis was AAV (17.14%); IC-MPGN, amyloidosis and NOS FSGS in 11.42% each; TIN and MN in 8.57%, each. Treatment was modified in 11 cases (31.4%) after obtaining a pathology diagnosis. (Fig. 1)

Conclusions: PKB in adults 65 years or older is a safe procedure, that provides a pathology diagnosis in most of the cases that may help modify treatment and prognosis in our patients. Advanced age should not be considered a contraindication for kidney biopsy.

Systemic Lupus Erythematosus and ANCA-Associated Vasculitis Presenting De Novo in the Puerperium

Odalina H. Marrero, Waleska D. Nuñez, Guillermo Alvarez, Ronald Valdez Imbert, Nicole A. Medrano. *Centros de Diagnostico y Medicina Avanzada y de Conferencias Medicas y Telemedicina, Santo Domingo, Dominican Republic.*

Introduction: Overlap syndrome of systemic lupus erythematosus (SLE) and ANCA associated vasculitis (AAV) is uncommon. Most patients have a worse renal presentation and require more aggressive treatment.

Case Description: A 38-year-old woman with a history of preeclampsia in her first and only pregnancy underwent a cesarean section 5 months ago and presented with chronic arterial hypertension during the gestation period. She is referred to the nephrology clinic for presenting muscle pain, oral ulcers, dyspnea, and foamy urine for 3 months. She presented with blood pressure in 136/89 mmHg, basal crackles in both lung bases, and stage III edema with pitting in lower limbs. The test showed a nephrotic syndrome with ANA and ANCA-P positive (Table 1). A renal biopsy showed pauci-immune crescentic lupus nephritis with AAV (Figure 1). Management began with pulses of intravenous corticosteroids for 3 days followed by prednisone, hydroxychloroquine, cyclophosphamide (6 doses). For 10 months the patient has had a good evolution (Table 1). Although in the 3rd month of treatment he was diagnosed with herpes zoster, which made it necessary to stop for 2 months and manage with mycophenolate mofetil.

Discussion: Overlap of SLE and AAV has been described in less than 3%. The use of steroids at high doses and cyclophosphamide or rituximab is necessary. SLE during pregnancy is difficult to quickly diagnose and when symptoms of preeclampsia persist after delivery, SLE should be ruled out.

Pauci-Immune Necrotizing Glomerulonephritis in Association with Chronic Hepatitis C

Bashirat O. Johnson, Mala Anna John, Hugo J. Villanueva, Lin N. Lwin, Jinil Yoo. Nephrology Unit, Montefiore Medical Center - Wakefield Campus, Bronx, NY. *Montefiore Medical Center, Bronx, NY.*

Introduction: Necrotizing glomerulonephritis (GN) is a severe form of glomerular injury associated with crescent formation, characterized by rapidly progressive impairment of renal function. It is usually caused by small vessel vasculitis and presence of circulating antineutrophilic cytoplasmic antibodies (ANCA). Chronic hepatitis C (HepC) rarely leads to ANCA associated necrotizing GN. We present a case of likely MPO-ANCA associated necrotizing GN with chronic HepC.

Case Description: A 58-year-old male with a history of type 2 diabetes, hypertension and chronic HepC, presented with cough and blood tinged sputum of 1 month. On admission, covid-19 was positive and Chest X ray showed a small right basal density, creatinine 1.54mg/dl, (0.80mg/dl 1 year prior), microhematuria and proteinuria (urine protein creatinine ratio - 965.5mg/g), with HepC viral load of 5,680,533 IU/ml. Serologic tests showed positive MPO-ANCA (>133 U/ml), ANA (>1:1280) and anti–dsDNA (21 U/ml). PR3-ANCA, rheumatoid factor and cryoglobulins were negative, C3 and C4 were normal. Kidney biopsy revealed pauci-immune focal segmental necrotizing GN in less than 20% of the glomeruli, suggestive of microscopic vasculitis. Additional findings were mild tubulointerstitial involvement with acute tubular necrosis. In view of necrotizing GN, likely related to HepC and relatively stable renal function, he was started on treatment for HepC, using Glecaprevir/pibrentasvir, without immediate immunosuppressive therapy. Follow up in 6 weeks showed serum creatinine down to 1.21mg/dl and remained stable, undetectable viral load, decreasing MPO-ANCA titers (from >133 U/ml to 99 U/ml, to 79 U/ml), negative ANA and anti DsDNA, but with persistent hematuria and proteinuria.

Discussion: This patient with untreated HepC, positive MPO-ANCA, ANA and anti-dsDNA, presented with acute nephritic syndrome. Kidney biopsy showed pauci-immune focal segmental necrotizing GN features consistent with MPO-ANCA associated disease. Even though immediate immunosuppressive treatment of necrotizing GN is required for improved renal outcomes, in our case, treatment was withheld in view of 2 active viral infections. HepC therapy was initiated with improvement in renal function, progressive reduction in MPO-ANCA titers and disappearance of ANA and anti-dsDNA positivity.

PUB245

An Atypical Case of Immune Complex-Mediated Glomerulonephritis

Klodia Hermez, Ryann Sohaney. *Henry Ford Hospital, Detroit, MI.*

Introduction: Rapidly progressive crescentic glomerulonephritis is an aggressive clinical syndrome characterized by massive loss in kidney function in a relatively short period of time, days to weeks. The etiology of this disease is varied, with subtypes including anti-glomerular membrane disease, immune complex-mediated injury, or pauci-immune. We report a rare case of acute exudative and crescentic glomerulonephritis leading to end-stage renal disease due to an unknown infection.

Case Description: A 28-year-old African American male with a medical history only remarkable for asthma presents with nausea, vomiting, diarrhea, and severe abdominal pain for 3-4 days. On admission, the patient's lab data showed a serum creatinine level of 12.28 mg/dL, BUN of 71, and WBC of 23,000. Renal ultrasound showed increased echogenicity of bilateral kidneys suggestive of medical renal disease. Non-emergent HD and kidney biopsy were ordered. COVID-19, flu A/B, hepatitis panel, ANA, c-ANCA, p-ANCA, and anti-GBM were all negative. Serum protein electrophoresis showed mildly elevated IgG lambda. C3 was mildly decreased, and C4 was normal. Blood cultures were negative. The patient was initiated on vancomycin/Cefepime/Metronidazole. Kidney biopsy demonstrated 14/16 glomeruli with necrotizing crescents, C3 predominant mesangial and capillary loop staining, and numerous mesangial and segmental endothelial humps.

Discussion: Patients with postinfectious glomerulonephritis and <50% glomerular involvement have a higher chance of mild disease and potential recovery, with >80% glomerular involvement documented as severe disease requiring therapy. This case represents ~87% glomerular exudative crescents due to an unknown cause, likely post-infectious. The patient was treated with pulse steroids x3 days, but no other immunosuppression was started as data is lacking in severe post-infectious GN as well as idiopathic immune complex RPGN. Initiation of oral or IV cyclophosphamide or rituximab was considered, however, was deferred and the patient was treated with steroid monotherapy. The patient remains on hemodialysis with no evidence of renal recovery. This case highlights the need for further studies in immunosuppression guidelines for patients with this debilitating disease.

PUB246

From Low Hemoglobin to Chronic Renal Failure: An Unusual Presentation of Advanced IgA Nephropathy in a Young Patient with Anemia

Leonardo R. Ramirez Botana. *Hospital de la Concepcion, San German, Puerto Rico.*

Introduction: IgA nephropathy is a leading cause of CKD and renal failure. The most common primary glomerulonephritis in the world among patients undergoing renal biopsy. Its diagnosis is associated with a reduction in life expectancy between 6 and 10 years.

Case Description: We describe a patient case presented to emergency room due to general weakness of 4 weeks evolution. Our patient, with a PMH of asthma, was diagnosis with severe anemia, and admitted due to progressive shortness of breath, moderate chest pain and severe acute renal failure. The patient was worsening clinically over a period of less than 1 hour at the emergency department, blood pressure was uncontrolled and renal failure worsening, for this reason an emergency renal replacement therapy was required. Laboratory tests showed anemia and severe renal failure with high anion gap metabolic acidosis. Urinalysis reported proteinuria, and moderate blood in urine. Testing for HIV, Hepatitis B, C, ANA, complements C3/C4, Anti Cyclic Citrullinated Peptides and serum free light chains were normal, except Glomerular Basement Membrane Ab that was out of range. A kidney biopsy was recommended and prednisone, plasmapheresis and therapy with Rituxan was started.

Discussion: Cases reviewed have been reported with IgA nephropathy associated with focal segmental glomerulosclerosis. Electron microscopy showed mesangial and subendothelial immune type electron dense deposit. Understanding the pathogenesis of IgA nephropathy reveals therapeutic targets. Mucosal IgA production by plasma cells occurs by T cell dependent and independent processes. B cell and plasma cell inhibitors such as rituximab, may result in decreased IgA production, using as part of the treatment in our patient. Complement inhibitors may prevent formation of immune complexes. This case will further contribute to the diagnosis and management of population of patients with Iga Nephropaty in Puerto Rico. Our patient was discharging home, to continue renal replacement therapy, and using a first line medication for aggressive blood pressure control and high-intensity statin therapy for hyperlipidemia and oral prednisone. She was set up for hemodialysis. There is a strong possibility of this patient is having a progressive course leading to ESRD, so early diagnosis and treatment are of key importance.

PUB247

A Case of Hydralazine, a Common Antihypertensive, Causing ANCA-Associated Vasculitis

Neela Qadir,[1] Nikolaj Kljusev,[1] Jaswinder Rathour,[1] Olena Bolotova,[1] Deepinder Osahan,[1] Surya V. Seshan.[2] [1]*Long Island Community Hospital, Patchogue, NY;* [2]*Weill Cornell Medicine, New York, NY.*

Introduction: Hydralazine is a vasodilator that is commonly used as an anti-hypertensive agent. Hydralazine induced ANCA vasculitis is a rare phenomena; with approximately < 100 cases reported.

Case Description: A 66-year-old male with significant PMHx of non-ischemic cardiomyopathy, HTN presented to the emergency department for hyperkalemia and worsening renal function. The patient otherwise had no complaints. It was noted that patient was on hydralazine 100mg twice daily. Initial vitals were BP 144/101, HR 86, Resp 16, O2 100% on RA, temperature 97.7F. The reminder of the examination revealed 2+ pitting edema in the lower extremities. Laboratory studies revealed BUN 89, Creatinine 5.95, K 6.0, Hgb 5.7, urinalysis was positive for large blood and >100 RBC cells. Of note it was found that the patient had worsening renal function for approximately two years with progressively worsening renal function from Cr 1.57 to present of 5.95. The patient had a CT abdomen pelvis w/o contrast performed which demonstrated edematous changes. The patient was started on a Lasix challenge and a glomerulonephritis work-up was sent out. The patient continued to have urine output; however due to progression of chronic kidney disease, was initiated on dialysis. The initial blood work sent out came back positive for MPO >8.0, ANA at 1:2560 and anti-histone antibodies >7. Vasculitis was high on the differential and hydralazine was held. The renal biopsy revealed crescentic GN, and diabetic/hypertensive changes with >50 % of IFTA, crescents in <50%. The immunofluorescence was consistent with pauci-immune disease. The patient received three days of pulsatile steroids, followed by Rituxan infusion. The remainder of the hospitalization was unremarkable.

Discussion: The mechanism of hydralazine induced ANCA vasculitis remains unknown- with multiple theories associated with MPO leading to neutrophil apoptosis. Typical symptoms include myalgia, petechiae. In cases of hydralazine-associated vasculitis- symptoms can include rapidly progressive renal dysfunction. Hydralazine associated vasculitis diagnosis is made via serologic measures including ANCA, MPO antibodies and anti-histone antibodies. Renal biopsy will demonstrate pauci-immune GN. Treatment would include cessation of hydralazine, pulsatile steroids, and immunosuppression with cyclophosphamide or rituximab.

PUB248

Proteomic Analysis of Lysine 2-Hydroxyisobutyryl in Systemic Lupus Erythematosus (SLE) Reveals Protein Modification Alteration in Complement and Coagulation Cascades and Platelet Activation Pathways

Fanna Liu,[1] Chaoying Kuang,[1] Yong Dai,[2] Donge Tang.[2] [1]*Nephrology, Guangzhou, China;* [2]*Clinical Research Center, Shenzhen, China.*

Background: Post-translational modifications (PTMs) are considered to be an important factor in the pathogenesis of systemic lupus erythematosus (SLE). Lysine 2-hydroxyisobutyryl (Khib), as an emerging post-translational modification of proteins, is involved in some important biological metabolic activities. However, there are poor studies on its correlation with diseases, especially SLE.

Methods: Khib levels in SLE patients and healthy controls were compared based on liquid chromatography tandem mass spectrometry, then proteomic analysis was conducted.

Results: Compared with healthy controls, Khib in SLE patients was up-regulated at 865 sites of 416 proteins and down regulated at 630 sites of 349 proteins. The site abundance, distribution and function of Khib protein were investigated further. Bioinformatics analysis showed that 11 Khib differentially modified proteins (DMPs) were significantly enriched in the Complement and coagulation cascades pathway. 23 Khib DMPs on the Platelet activation pathway were significantly enriched.

Conclusions: Khib in PBMCs of SLE patients was significantly up- or down-regulated compared with healthy controls. Khib DMPs in the Complement and coagulation cascades and Platelet activation pathways affect platelet activation and aggregation, coagulation functions in SLE patients, and may play an important role in the pathogenesis of SLE. This result provides a new direction for the possible significance of Khib in the pathogenesis of SLE patients.

Phenotypic Characteristics of Monocytes and Macrophages in Lupus Nephritis with Bacterial Antigen Induction

Michal Komorniczak, Tomasz A. Jarzembowski, Barbara Bullo-Piontecka, Agnieszka E. Daca, Alicja Debska-Slizien. *Gdanski Uniwersytet Medyczny, Gdansk, Poland.*

Background: Monocytes and macrophages play crucial roles in the innate immune system. Systemic lupus erythematosus is an autoimmune disease with diverse manifestations, including lupus nephritis (LN), where monocyte and macrophages (M&M) are believed to be involved in the pathogenesis. Understanding their role in LN remains challenging. This study aimed to compare the phenotypic characteristics of M&M in patients with LN, specifically focusing on their response to bacterial antigens.

Methods: 12 patients with biopsy-proven LN and 3 healthy volunteers (HG) were enrolled. The LN group consisted of 11 females and 1 male, aged 28-67 years (mean:48). Disease activity was assessed using SLEDAI and SLAM-R scores, while serum creatinine and daily proteinuria were measured as markers of kidney involvement. Monocytes were magnetically isolated from PBMC and cultured under 3 conditions: without bacteria, with Escherichia coli or Enterococcus faecalis. The cells were evaluated at 4-time-points (4, 8, 10, 12 days). We examined monocytes (CD14+ and CD14+CD16+ phenotype) and macrophages (pro-inflammatory M1[CD68+CD80+] and anti-inflammatory M2[CD68+CD163+]).

Results: Our findings revealed consistent behavior of CD14+ cells in HG, where their percentage decreased over time. In LN patients, the decrease was more expressed in samples exposed to bacteria, particularly E. coli. CD14+CD16+ monocytes were significantly lower at each time-point in samples with bacterial exposure, indicating reduced reactivity in LN. M1&M2 macrophages increased over time in non-exposed groups, but LN M1 cells decreased from day 8 in samples with bacterial induction. LN M2 decrease was observed even earlier, especially with E.faecalis exposure. These results demonstrate differential behavior of M&M in LN patients compared to healthy individuals when exposed to bacterial antigens. The low percentage of M1 cells in LN samples with bacterial antigens suggests faster activation in LN patients, occurring as early as day 1-3 of incubation.

Conclusions: This study highlights the phenotypic differences in M&M in LN patients, particularly in response to bacterial antigens. Further investigation into the mechanisms underlying these differential responses could provide valuable insights into the pathogenesis of LN and potential therapeutic targets.

JAK/STAT Expression in Patients with IgA Nephropathy

Mateus J. Luvizotto,[1] Cristiane B. Dias,[1] Lectícia Jorge,[1] Luis Yu,[1] Renato C. Monteiro,[2] Niels O. Camara,[3] Viktoria Woronik.[1] [1]*Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil;* [2]*INSERM, Paris, France;* [3]*Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: The JAK/STAT signaling pathway is an intracellular signal transduction pathway, that is involved in diverse biological processes, including cell proliferation, differentiation, apoptosis and regulation of the immune system. Recent studies have explored abnormal receptor tyrosine kinase activation in the pathogenesis of IgA nephropathy(IgAN).

Methods: A retrospective analysis was performed on all IgAN patients diagnosed by kidney biopsy. Clinical and laboratory data were collected at baseline and at the end of follow up. Kidney tissue sections were stained with antibodies specific for components of JAK/STAT pathway. We included 63 patients with IgAN and compared with 6 controls.

Results: Staining for JAK3 was observed observed in the renal tubule and glomeruli. Staining for JAK3 was enhanced in patients with IgA nephropathy compared to controls. The expressions of JAK2, pSTAT and STAT3 were analyzed, but there was no significant

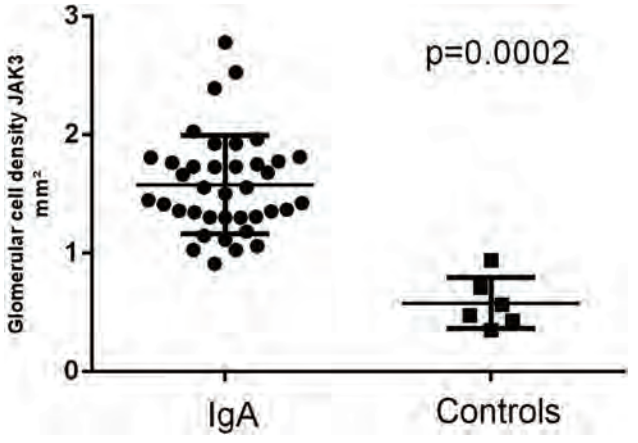
marking in the glomerulus. Correlations of JAK3 cell density with markers such as creatinine, proteinuria, as well as the MEST score were performed, but without significant results.

Conclusions: The presence of activation of the JAK/STAT signaling pathway has been demonstrated in patients with IgAN. This pathway may represent a therapeutic target in this pathology.

Clinical and laboratory data at the time of biopsy and at the end of follow-up

Age	33.00 [24.50-46.00]
Women(%)	35 (55.6)
CKD-EPI baseline mL/min/1,73 m2	58.00 [31.00, 95.00]
Remission (n/%)	31 (54.4)
Outcome (n/%)	19 (31.1)

The primary outcome was defined as end-stage renal disease (ESRD) or doubling of baseline creatinine. Remission has been defined as 50% reduction in baseline proteinuria and <3.5 g/day.



Comparison of JAK3 cell density in patients with IgA and controls

PUB251

Diffuse Alveolar Hemorrhage Presenting in IgA Nephropathy

Crystal K. Jobson, Randy L. Luciano, Anushree C. Shirali, Grace L. Malvar. *Yale School of Medicine, New Haven, CT.*

Introduction: Immunoglobulin A nephropathy (IgAN) is the most common glomerulopathy worldwide. Clinical presentation of IgAN ranges from isolated hematuria to progressive glomerulonephritis and more rarely as pulmonary-renal syndrome. Here, we describe a case of diffuse alveolar hemorrhage (DAH) accompanying IgAN.

Case Description: A 38-year-old female with a history of end-stage liver disease secondary to alcohol-related cirrhosis, presented with oliguria and abdominal distention. Labs showed creatinine of 2.7 mg/dL (baseline 1.2), red blood cells on urine microscopy, urine protein to creatinine ratio of 7.13 mg/mg and diagnostic paracentesis was negative. ANA was positive with titers of 1:40, low C3/C4, but other serologic markers were negative, including Anti-Smith, MPO, and PR3. During hospitalization, she developed hypoxemic respiratory failure with hemoptysis. Chest CT showed diffuse alveolar opacities concerning for DAH. She was electively intubated, and BAL confirmed DAH. She received pulse steroids for four days, followed by two days of 0.5 mg/kg steroids, and underwent an ultrasound-guided kidney biopsy confirming IgAN with acute tubular injury. Due to steroid-associated delirium, immunosuppression was switched to Mycophenolate Mofetil with marked improvement in pulmonary symptoms. The patient required temporary hemodialysis to manage AKI with electrolyte derangements and volume overload. Before discharge, she achieved renal recovery sufficient to discontinue hemodialysis. Creatinine has remained at 0.9-1.0 mg/dL four months after presentation.

Discussion: This case suggests that IgA nephropathy should be included in the differential diagnosis of DAH and emphasizes the importance of a timely renal biopsy in patients with pulmonary-renal syndrome. Although initial steroid treatment can be limited due to poor tolerance, quick transition to targeted immunosuppression, such as Mycophenolate Mofetil, can result in significant clinical response in individuals with progressive Ig A nephropathy.

PUB252

Active Components of Traditional Chinese Medicine for IgA Nephropathy, Shen Ping, Include Mixed-Linkage Glucans That Inhibit Cell Proliferation and Signaling in Human Mesangial Cells Induced by Platelet-Derived Growth Factor (PDGF)

Zhi qiang Huang,[1] Xianwen Zhang,[2] Stacy D. Hall,[1] Qing Wei,[1] Janet Yother,[1] Lin Wang,[2] Dana V. Rizk,[3] Bruce A. Julian,[3] Yiping Chen,[2] Jan Novak.[1]
[1]University of Alabama at Birmingham, Department of Microbiology, Birmingham, AL; [2]Longhua Hospital affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China; [3]University of Alabama at Birmingham, School of Medicine, Birmingham, AL.

Background: Shen Ping (SP), a prescribed traditional Chinese medicine, has been used for decades to treat IgA nephropathy in China. Our prior studies showed that SP inhibits PDGF-induced cellular proliferation and signaling in primary human mesangial cells. However, identity of the active components in SP is unknown. We report the chemical nature of the SP components that inhibit PDGF-induced activation of mesangial cells.

Methods: Human mesangial cells in 96-well plates were serum-starved for 24 h and SP or SP-derived purified components were tested for capacity to inhibit PDGF-induced proliferation. Signaling tests used confluent serum-starved mesangial cells stimulated with PDGF-BB for 15 min in the presence or absence of SP or SP-derived components. Cell lysates were then analyzed with SDS-PAGE immunoblotting to assess changes in phosphorylation of selected proteins. Active SP compounds were isolated by chromatographic and physical-separation methods and then characterized by physical and enzymatic methods combined with the assessment of biological activity in mesangial cells.

Results: The active SP components, precipitated and concentrated using a 10-kDa cut-off ultrafilter, inhibited PDGF-induced cellular proliferation and phosphorylation of ERK, Axl, and Akt. These compounds were heat-resistant and likely consisted of polysaccharides. β1,3-exoglucanase removed β1,3-glucans without impacting the anti-PDGF activity. Conversely, an endoglucanase (lichenase) that cleaves mixed-linkage glucans inactivated most of the anti-PDGF activity. Thus, the active compounds in SP are mixed-linkage glucans. To further characterize them, we produced a β1,3-exoglucanase-digested SP sample and performed size-exclusion chromatography. Active fractions analyzed by high-performance anion-exchange chromatography coupled with pulsed amperometric detection identified a series of polysaccharides. Lichenase digestion removed most of the polysaccharide material while producing shorter oligosaccharides.

Conclusions: The active compounds in SP are mixed-linkage glucans. Future experiments will determine their detailed structures and mode of action.

PUB253

A Case of Crohn Disease-Related Tubulointerstitial Nephritis

Neev Patel, Oluwadamilola Adisa, Maheen Khan, Yashvi Pethani, Adrian P. Sequeira. *LSU Health Shreveport, Shreveport, LA.*

Introduction: The prevalence of extraintestinal manifestations (EIM) in Crohn's disease (CD) varies and can involve almost every organ. Renal involvement in patients with IBD is not uncommon, with varied manifestations. Nephrolithiasis, tubulointerstitial nephritis (TIN), glomerulonephritis (GN), and amyloidosis are the most common manifestations. Although most cases of TIN have been associated with 5-ASA, and cyclosporin A agents underlying immune pathophysiology could directly involve the kidney as well. We describe a biopsy-proven case of TIN most likely secondary to CD and less likely to drug exposure.

Case Description: A 59-year-old woman with a background of hypertension (HTN) and stable CD on infliximab infusions for about 2 years was referred to Nephrology after a hospital admission for AKI originally thought to be due to uncontrolled HTN. On investigation, renal function drastically decreased over 9 months with a serum Cr increase from 0.8mg/dL to 2.7mg/dL. Urine Analysis was unremarkable without cells or proteinuria. A renal biopsy showed 4/15 glomeruli with global sclerosis. Focal lymphocytic inflammatory in the interstitial compartment associated with rare eosinophils and focal tubular injury confirmed TIN with 30-40% interstitial involvement. It also showed significant thickening of arterioles with ischemic changes in glomeruli, and no immune deposits on immunofluorescence or electron microscopy. TIN was treated with oral steroids for four weeks with tight BP control. No improvement after steroids was seen along with worsening of her CD. A week after resumption of Infliximab therapy her Cr stabilized to 2.4mg/dL followed by 2.1mg/dL a month later.

Discussion: It is difficult to establish whether renal dysfunction is secondary to CD itself or medical treatment. However, recent literature highlighted the link between TIN and IBD. Prompt and thorough evaluation of AKI in patients with IBD via a kidney biopsy with judicious use of therapeutic agents is warranted. Infliximab appears to have low risk of TIN. Even in absence of intestinal flare, kidney injury could have occurred as EIM of CD. Excluding other acute and chronic etiologies of TIN, and improvement in renal function after infliximab, Crohn's disease related TIN was likely the cause of interstitial kidney injury in our patient.

PUB254

Focal Segmental Glomerulosclerosis with Glomerulomegaly as a Rare Complication of Testosterone Replacement Therapy

Amira S. Kamboj,[1,2] Sumugdha Rayamajhi,[1] Shailendra Sharma,[2] Nader Kassis Akl.[2] *[1]Michigan State University, East Lansing, MI; [2]Sparrow Health System, Lansing, MI.*

Introduction: Testosterone replacement therapy (TRT) is the mainstay of treatment for hypogonadism in male adults. Androgenic-anabolic steroids (AAS) are all synthetic derivatives of the hormone testosterone and include those used illegally as performance enhancing drugs. The main differences between TRT and illegal AAS abuse is the dosing, proper supervision by a health care provider and purity of the drugs, however the compounds used are often similar if not identical. Focal segmental glomerulosclerosis (FSGS) is a common cause of nephrotic syndrome, it accounts for about 40% of cases in adults and 20% in children. FSGS has been linked to long-term AAS abuse. There have not been any documented cases of the development of FSGS in adult male patients with hypogonadism on long term TRT.

Case Description: A 51-year-old man with a history of chronic kidney disease stage 3, hypogonadotropic hypogonadism on chronic TRT, hypertension and chronic hepatitis C was sent by his nephrologist to a local Emergency Department (ED) in January 2023 after lab work revealed a significant increase in creatinine from his baseline of 1.7 mg/dL to 3.19 mg/dL. On arrival his vital signs were stable. He denied any acute symptoms or changes in his health. Serological workup was unrevealing. He was taking testosterone propionate 25 mg daily intramuscularly for hypogonadism, somatropin 1.6 mg daily intramuscularly for growth hormone deficiency. Renal biopsy was obtained to determine the cause of the patient's renal failure. Pathology from renal biopsy showed focal segmental glomerulosclerosis with glomerulomegaly. The patient was instructed to speak with his endocrinologist about lowering the dose and even discontinuing testosterone therapy.

Discussion: The beneficial effects of TRT in the treatment of male hypogonadism are widely known, however the risks and complications of long-term use have not been as widely studied. Both FSGS and glomerulomegaly have been described among bodybuilders with long term AAS abuse. Our case highlights the need for further research on the renal complications of TRT.

PUB255

Unique Case of Fibrillary Glomerulonephritis

Ujjwala Murari,[1] Khaled Shawwa,[1] Prathap Simhadri,[2] Mark A. Poling.[1] *[1]West Virginia University, Morgantown, WV; [2]AdventHealth, Atlamonte Springs, Daytona Beach, FL.*

Introduction: Fibrillary Glomerulonephritis (FGN) accounts for approximately 0.5-1% of all adult Glomerulonephritis cases on Renal Biopsy. FGN is characterized by the deposition of Microfibrils 10-30nm in diameter in the mesangial and Glomerular capillary walls and is often found in patients with a history of diseases, including Cancer, Autoimmune diseases, and Hepatitis C. The diagnosis of FGN is usually made with a Kidney biopsy with a pathognomonic finding of DNAJB9 staining.

Case Description: A 69-year-old white woman with a past medical history significant for morbid obesity (BMI-55), hypertension, and type 2 diabetes mellitus was referred by her PCP due to a decline in Renal function with a rise of her serum creatinine up to 2.6 mg/dl(baseline was 1.3 in 2021). Her rise was slow over six months, with a change in GFR from 55 to 19 with minimal proteinuria and no lower extremity edema. She had no history of NSAID, herbal, or Supplemental usage and had no Family history of Renal disease. Upon evaluation, her serum albumin was 3.6 gram/deciliter, and the protein creatinine ratio was 327mg/gram on random urine. Serological studies were negative for HIV and Hepatitis C. SPEP, UPEP, and serum-free light chains were nonrevealing. C3 and C4 complements were normal. Cryoglobulin was negative. Renal USG showed 12 x 5 cm bilateral kidneys with normal Echogenicity and Cortical thickness. Renal biopsy: Light Microscopy: Mesangial matrix expansion noted, no definite nodules, endocapillary hypercellularity, or crescent formation: no RBC or atypical casts. Immunofluorescence showed Smudgy, Mesangial reactivity in the glomerulus for Ig G 3+, C3(1+), Kappa light chain 3+, and lambda light chain 3+. Electron Microscopy: Segmental deposition of fibrillar material 12-25 nm in diameter. The immunohistochemical stain was positive for DNAJB9.

Discussion: We report a 69-year-old white woman well-controlled diabetes with minimal proteinuria. Unfortunately, the Kidney biopsy showed FGN. Although her loss of kidney function was gradual in the setting of minimal proteinuria, her diabetes could not explain decline in her renal function; a kidney biopsy changed the management of this patient. Kidney biopsy remains the gold standard for the diagnosis of kidney pathology. It is safe and allows us not to miss a major Glomerular disease. We plan to treat her with Rituximab Immunosuppressive therapy to prevent the disease's progression.

PUB256

Membranous Nephropathy Relapse After 26 Years

Abdulrahman A. Alwagdani,[1] Emaad M. Abdel-Rahman.[2] *[1]Security Forces Hospital Program Makkah, Makkah, Saudi Arabia; [2]University of Virginia, Charlottesville, VA.*

Introduction: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in non-diabetic white males older than 40 years. Primary MN is diagnosed in 80% of all cases and is characterized by the presence of PLA2 R antibodies in 80% of cases. Relapse of MN after treatment is common however most relapses happen within the first 5 years. We present a rare case of MN relapse after 26 years of remission.

Case Description: A 68 years old male with past medical history of primary MN diagnosed on 1995, CKD stage II, hypothyroidism, T2DM, HTN and obesity was referred to the nephrology clinic for worsening albuminuria on May 2021. He had history of MN on 1995 that was treated with Prednisone and Cyclophosomide. He had been on remission since that time with regular nephrology follow ups. When he presented to the nephrology clinic he reported frothy urine for 3 months. **Physical exam:** Vitals, cardiovascular, lungs and abdominal exams were unremarkable. No lower extremities edema. **Investigations:** BUN 9 mg/dl Cr 0.9 mg/dl Albumin 3.2 HbA1c 10.2 Urine Albumin Creatinine Ratio 1470 mg/g **Clinical course:** He was started on Losartan with improvement in albuminuria from 1470 to 900mg/g. On September 2021, albuminuria worsened to 4g/g. Serology was remarkable for +ve anti PLA2 R. A kidney biopsy showed subepithelial immune complex-type dense deposits and moderately sclerotic arteries and severely hyalinized arterioles. His Cr was mildly elevated to 1.4 and albuminuria decreased from 4g/g to 2g/g however on December 2021 he started to have worsening edema with rise of Cr to 2.5 and albuminuria worsened to 13g/g. On March 2022 he was started on weekly Rituximab and completed 4 doses. His Cr peaked at 2.6 and then started to trend down after Rituximab to 1.2-1.4 however he continued to have persistent nephrotic range proteinuria.

Discussion: We report a patient with primary membranous nephropathy relapse after 26 years. MN relapse is rare after 5 years and cases of relapse after 20 years of remission are extremely rare. The biopsy showed features of MN and diabetic kidney disease. Despite maximally tolerated Losartan dose, he continued to have worsening Cr and proteinuria. His Cr improved after Rituximab however he had persistent proteinuria. The decision to use Rituximab rather than CNI was due to poorly controlled diabetes. Diabetic kidney disease is likely a factor in the failure of MN remission in our patient.

PUB257

Complement Dysregulation and Volume Excess Hyponatremia in Pre-Eclampsia

Sana Fatima, Umair Khan, Marat Abdullin, Gregory L. Braden. *UMASS Chan Med School-Baystate, Springfield, MA.*

Introduction: Complement abnormalities may occur in pre-eclampsia but their significance has not been completely elucidated. Hyponatremia occurs in severe pre-eclampsia but the mechanisms causing this are unknown. Some investigators suggest that SIADH is the cause but Hayslett suggests that volume excess hyponatremia is the most important cause. We describe a patient with pre-eclampsia who presented with severe nephrotic syndrome, edema and 14 g proteinuria & hyponatremia. She had a CFH variant but no complement deposition on renal biopsy.

Case Description: A 29-yo presented at 25+3 weeks gestation had hypertension and clinical volume overload. She had a BP of 150/90 with ankle swelling and hemoglobin 8.6 g/dL, platelets 174 k/mm3 & S. creatinine 1.3mg/dL. Urinalysis showed microscopic hematuria with Tp/cr ratio 14 g/dl. Labs showed: Na 132 meq/L, K 5.6 meq/L, Cl 105 mEq/dL, HCO3 21 meq/L, BUN 29 mg/dL & S.uric acid was normal at 6.4 mg/dL and urine specific gravity was 1.024 equivalent to urine osmolality to 700 Osm. LDH was 449 IU/ml, haptoglobin 69 g/dl, ADAMST13 was normal, ANA negative, anti-dsDNA positive at 14, and other auto immune workup was negative. C4 complement nadired at 5 mg/dL, with a C3 level of 107 mg/dL. Due to the low C4 complement, dsDNA and proteinuria, a diagnosis of lupus nephritis was made & she received pulse dose steroids for 3 days. Complement genetic testing showed a CFH variant. Factor H, factor I, factor B, CD46 expression were all normal. A renal biopsy showed glomerular endothelial swelling & no immune complexes by IF or EM. Findings showed thrombotic microangiopathy (TMA) consistent with pre-eclampsia. An urgent C-section was performed. Serum Na & edema rapidly corrected to normal without diuretics with resolving proteinuria & complete recovery of renal function.

Discussion: Complement dysregulation occurs in pre-eclampsia and eclampsia. In our case, despite a genetic study confirming a CFH variant, no complements were seen in the renal biopsy which was a surprise. This suggests serum complement dysregulation in pre-eclampsia may not be involved in intrarenal TMA. In addition, our case suggests that nephrotic syndrome extracellular fluid volume excess is the cause for hyponatremia in severe preeclampsia. Prompt delivery of hyponatremic patients with pre-eclampsia leads to rapid improvement of the serum Na without diuretics.

PUB258

A Rare Case of Renal-Limited Hydralazine-Induced Pauci-Immune Glomerulonephritis

Yahya Al-Yousif, Amenah Al-Juboori, Nitin Behl, Naresh Kumar. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: RPGN is characterized by a rapid decline in renal function with significant hematuria and proteinuria. Pauci-immune GN predominantly presents as granulomatosis with polyangiitis, 90% have ANCA antibodies, hence the name ANCA-associated vasculitis. Hydralazine has been used since the 1950s for the management of hypertension. Evidence for hydralazine-associated vasculitis dates to the pre-ANCA era.

Case Description: A 58-year-old man with CKD IV, HTN, CVA, and polysubstance usage presented with chest pain, accelerated hypertension, cough, and SOB. Creatinine 6.75 mg/dl, bicarb 15 mmol/L, urine P/C ratio 5 gm/gm, procalcitonin 1.17 ng/mL, and hemoglobin of 5.7 gm/dl. Of note, the patient was recently started on hydralazine outpatient. The patient received antibiotics, blood, and was admitted to the step-down unit. The renal US revealed diffused renal echogenicity. Started on RRT, GN serologies revealed mildly positive RF, increased C-ANCA and MPO Abs, positive dsDNA, and negative Anti-PLA2R and complement, elevated SFLC and polyclonal gammopathy,

but no monoclonal spike. Anti-histone Abs was mildly positive, hydralazine was discontinued. Renal biopsy revealed total glomeruli 31, global glomerulosclerosis 18, moderate interstitial fibrosis with tubular atrophy, and severe arterial intimal fibrosis. One of four nonsclerotic glomeruli showed fibrin and small crescent formation. The patient was not placed on a pulsed dose steroid due to active infection and was started on prednisone 60 mg daily instead. Outpatient TRUXIMA (rituximab) was started.

Discussion: Pauci-immune GN accounts for up to 80% of RPGN occurrences, affecting 7–10 per million Americans per year. PICG has 80% 1-year mortality without therapy. 5-year survival is 75% with strong immunosuppression. Hydralazine-induced pauci-immune GN is rare; we present this case to highlight several critical aspects of drug-induced pauci-immune GN that can aid with early identification and improve patient outcomes. Early detection of MPO Abs helps diagnose the condition and timely kidney biopsy can guide adequate treatment. The offending agent must be discontinued early. Untreated RPGN evolves to ESRD in days to weeks. Prompt diagnosis and treatment enhance prognosis. We recommend serologies and, if inconclusive, a kidney biopsy. A patient with RPGN-suggestive symptoms needs a clear and urgent diagnosis and treatment.

PUB259

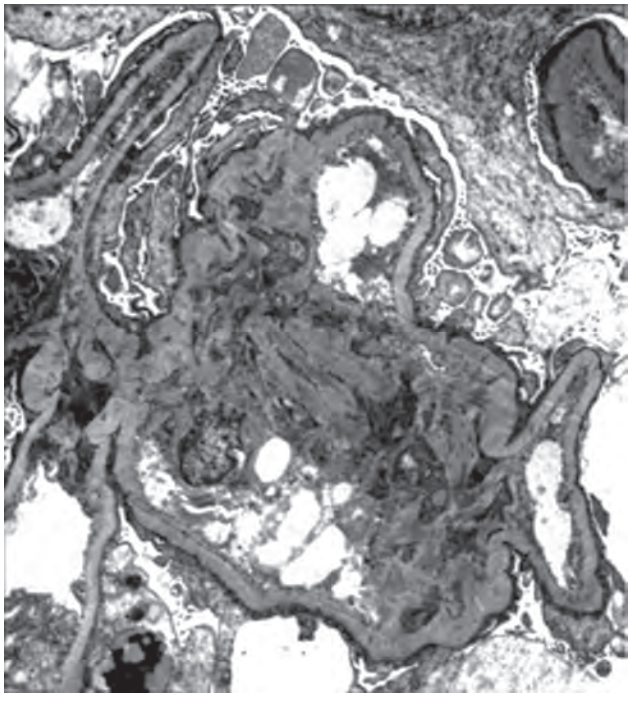
Unanticipated Cause of Minimal Change Disease: A Rare Case due to Hypothyroidism

Yahya Al-Yousif, Amenah Al-Juboori, Charles Nnewihe. *AtlantiCare Regional Medical Center, Atlantic City, NJ.*

Introduction: Hypothyroidism, also called underactive thyroid, may affect renal physiology and impair kidney function, among other metabolic implications. In certain case studies, hypothyroidism was mentioned as a contributing factor to minimum change disorder, which we will be emphasizing here.

Case Description: An 82-year-old female with PMH of Graves' disease s/p thyroidectomy, non-compliant with Levothyroxine presents to the ED with a complaint of edema, mainly in the lower limbs, slowly worsening over 2 weeks, as well as foamy urine. Laboratory workup showed a high TSH of 65.2 uIU/ml, a normal FT4, and a low FT3 of 0.4 pg/ml, creatinine of 4.35 mg/dl, hypoalbuminemia, and hyperlipidemia, urinalysis showed >500 protein, urine P/C was 3. A Glomerulopathy workup was begun. After ruling out autoimmune kidney disorders, a renal biopsy was done, confirming Minimal Change disease. Prednisone 60 mg and Levothyroxine 125 mcg were prescribed. Three weeks later, he demonstrated a favorable response to treatment with an improvement in symptoms and a repeat creatinine of 3.8.

Discussion: Inadequate supply of thyroid hormone can impair kidney function by influencing vascular resistance, the re-absorptive process, and renal blood flow. It can also influence the RAAS system, beta-adrenergic receptors, and renal tubular cell's dopaminergic activity. Gradual deterioration of kidney function causes an increase in the loss of free and bound thyroid hormones, ultimately increasing thyroxine need. GFR is reversibly lowered (by roughly 40%) in more than 55% of hypothyroid people. Thyroxine therapy reduces edema, albumin capillary permeability, and plasma colloid osmotic pressure. Because just a few isolated incidences have been documented in the literature, more study is needed to identify the link between hypothyroidism and nephrotic syndrome.



PUB260

Unilateral Parotid Swelling as the Initial Manifestation for HIV-Associated PLA2R-Negative Membranous Nephropathy

Ramsha Riaz,[1] Katrina K. Au,[1] Gregory F. Crisafulli,[2] Shreyaska Dahal,[2] Craig R. Goldstein.[1] *[1]Jersey City Medical Center, Jersey City, NJ; [2]St George's University School of Medicine, St George's, Grenada.*

Introduction: There are two major types of HIV-associated renal disease: HIV-associated nephropathy, which is more common, and HIV-associated immune complex disease. Kidney biopsy is necessary to differentiate between these types as they appear different histologically and may be beneficial to determine overall prognosis. We present the case of a patient with unilateral, painless swelling of the parotid region, who not only had underlying HIV infection but also full-blown renal failure requiring hemodialysis.

Case Description: A 34-year-old African-American male with no medical history presented to the hospital for worsening right-sided parotid swelling at the mandibular angle for 1 week. He also endorsed generalized malaise, intermittent shortness of breath, subjective fevers, and unintentional weight loss. Physical exam showed a soft, non-tender, mobile right-sided parotid mass. Labs were remarkable for profound renal dysfunction (BUN/Cr 92/9.71 mg/dL) and significant hyperkalemia with non-anion gap metabolic acidosis. Urinalysis revealed a protein-creatinine ratio 931 mg/g and 24-hr urine protein of 862 mg/dL. Imaging of the neck showed a well-marginated 3.4x3.0x3.6 cm, hypo-attenuated structure in the right parotid tail. He tested positive for HIV and syphilis. Hemodialysis (HD) was initiated. Drainage of the parotid mass was consistent with a lymphoepithelial cyst with no evidence of malignancy on biopsy. Kidney biopsy revealed burnt-out phase of membranous nephropathy, PLA2R negative, with presence of tubular microcysts on light microscopy, podocyte foot process effacement and tubuloreticular inclusions on electron microscopy. The patient was initiated on treatment for HIV and syphilis. After 4 months of treatment, his HIV viral load was undetectable with improvement in renal function and urine output allowing us to hold HD. Patient is currently maintaining a stable creatinine off HD.

Discussion: HIV poses a threat for the development of both acute and chronic kidney disease. It is imperative to consider the possibility of undiagnosed HIV infection in a patient presenting with painless cysts of the head and neck region. Furthermore, in cases of suspected HIV-associated nephropathy, obtaining a biopsy is clinically significant to not only provide a histological diagnosis but also aid management and prognosis.

PUB261

Granulomatosis with Polyangiitis in a Diabetic Woman with Nephrotic Proteinurias: Case Report

Waleska D. Nuñez, Odalina H. Marrero, Ronald Valdez Imbert, Guillermo Alvarez. *Centros de Diagnostico y Medicina Avanzada y de Conferencias Medicas y Telemedicina, Santo Domingo, Dominican Republic.*

Introduction: Granulomatosis with polyangiitis (GPA) is an antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides (AAV) is partof a group of disorders. All are associated with ANCA, affect predominantly small-sized arteries, in which it can present with pulmonary hemorrhage, deterioration of renal function, constitutional symptoms that can lead to death if not treated in time.

Case Description: A 71-year-old female with a known morbid history of Diabetes mellitus 2 + systemic arterial hypertension + grade II morbid obesity + hypothyroidism; which she was being investigated by hematology for approximately 3 two months for normochromic normocytic anemia + thrombocytosis + leukocytosis. She herself began to notice foamy urine and asthenia with normal kidney function and that is when she is referred to nephrology. Protein dosage is performed in 24-hour urine (5.2/24hrs) with C-Anca: weakly positive. It was decided to perform a renal biopsy and while waiting for it, the patient developed fever, cough, and respiratory distress that required CPAP 1 week later, and she was admitted to the intensive care unit. A diffuse pattern with opacities is evident on radiography with tomographic data suggestive of pulmonary hemorrhage and rapidly progressive deterioration of renal function. (Family members refused to perform bronchoalveolar lavage by bronchoscopy). A biopsy was received reporting granulomatosis with polyangeitis. Treatment with cyclophosphamide and rituximab plus steroids was started.

Discussion: After initiating pulses of steroids, cyclophosphamide, and rituximab, the patient remains in the intensive care unit for approximately 3 weeks due to impaired ventilatory mechanics. Subsequently, she is transferred to the clinical ward and her discharge is decided. Outpatient management continues. During the 3rd dose of cyclophosphamide, she presented severe neutropenia + fever + complicated urinary tract infection where she was in sepsis and required admission to the intensive care unit again and placement of colony stimulants. She is admitted in stable condition, treatment continues after her discharge. Until now, a patient with normal renal function, with a decrease in proteinuria by approximately 50%, with a significant improvement in its clinical picture.

PUB262

Infection-Related Pauci-Immune Golmerulonephritis: To Treat with Immunosuppression or Not, That Is the Question

Katherine E. White, Sanjivani Shrestha, Derek M. Fine, Samir C. Gautam. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Pauci-immune glomerulonephritis is a common cause of crescentic or rapidly progressive glomerulonephritis. Treatment typically consists of immunosuppression; however, we present a case of pauci-immune glomerulonephritis treated without immunosuppression.

Case Description: An 84-year-old female with medical history of breast cancer status post resection and chemoradiation, chronic lymphocytic leukemia with treatment-related myelodysplastic syndrome, and recent SARS-CoV-2 infection with central venous port-related coagulase negative staphylococcus bacteremia developed acute kidney injury. Urinalysis revealed proteinuria and hematuria. Urine sediment analysis showed dysmorphic red blood cells and red blood cell casts. Serologic studies were notable for hypocomplementemia, ANA, and c-ANCA; however, myeloperoxidase and proteinase 3 were negative. Kidney biopsy was performed. Light microscopy showed focal segmental glomerular necrosis with small crescent. Immunofluorescence performed on frozen sections showed a full house picture, but immunofluorescence performed on paraffin sections only showed 1-2+ mesangial staining for IgM. However, there were no electron dense deposits on electron microscopy which is most consistent with pauci-immune glomerulonephritis. Despite rising creatinine, immunosuppression was not started in the setting of persistent bacteremia and was planned to be started once blood cultures were negative for more than 48 hours. Once blood cultures became negative, creatinine started to stabilize. Creatinine peaked at 4.9mg/dL. Ultimately, steroids were not started given that creatinine continued to improve with antibiotics once blood cultures remained negative.

Discussion: Pauci-immune glomerulonephritis has been reported in cases of infective endocarditis and treated with antibiotics. This case highlights infection as a possible cause of pauci-immune glomerulonephritis with antibiotics being the mainstay of therapy in such cases.

PUB263

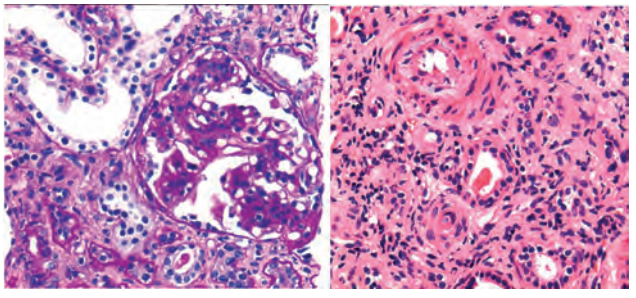
Methamphetamine-Associated Thrombotic Microangiopathy

Nayeli N. López Villa, Giovanna Y. Arteaga Muller, Rita B. Aguilar, Elisa M. Guerrero Gonzalez, Mara C. Olivo Gutierrez, Ricardo A. Garza Treviño. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Introduction: Thrombotic microangiopathy (TMA) is characterized by clinical presentation with microangiopathic hemolytic anemia, thrombocytopenia, and target organ damage. It can present acute kidney injury with damage and occlusion of the glomerular circulation. The requirement of renal replacement therapy has a poor prognosis.

Case Description: 16-year-old male, with no known pathological history. He has a history of drug use such as crack and methamphetamine. Brought in due to a month-long condition with nausea, cough with expectoration, dyspnea, and edema of the lower limbs. Upon admission to the emergency room, a patient was received with blood pressure 190/80mmHg, HR112bpm, 35 rpm, temperature 36.9°, saturation 95%, hemoglobin 5.5gr, platelets 72,000, BUN 149mg/dL, Cr19.6mg/dL, and potassium 6.1mEq. In its gasometry with pH 7.31 HCO3 12.6. Urinary sediment was obtained with a leukocyte cast, without dysmorphic erythrocytes. In renal ultrasound with adequate renal measurements, it was decided to carry out a renal biopsy. Image 1: expansion of the mesangial matrix with segmental proliferation, folded and healed basement membranes, with duplicated segments, leukostasis, karyorrhexis, and fibrin thrombi, partially organized and incorporated into the walls. Image 2: preglomerular, interstitial, and small-caliber arteriolar vessels with obliterative concentric thickening, advanced fibromyxoid intima, endothelial edema, and fibrin debris adhered to the walls. The biopsy also showed grade III chronic interstitial damage, and chronic glomerular hypoperfusion with advanced sclerosis, so it was decided to start hemodialysis as renal replacement therapy.

Discussion: In this case, we are dealing with thrombotic microangiopathy with severe renal involvement. MAT can have primary and secondary causes. In this patient, primary causes were ruled out, and secondary causes could only be associated with the use of deoxyephedrine (methamphetamine), a cause of CKD in a small population group that, on occasion, cannot be diagnosed.



PUB264

C3 Glomerulopathy in Kidney Transplant: A Case Report

Punith C. Chirumamilla,[1] Charles Russell,[2] Naveen Punchayil Narayanankutty,[2] Kartikeya Srivastava,[3] Saeed Suleiman.[4] *[1]Guntur Medical College, Guntur, India; [2]University of South Florida, Tampa, FL; [3]Srivastava Orthopaedic and Fracture Centre, Agra, India; [4]Al Balqa Applied University, Al-Salt, Jordan.*

Introduction: Membranoproliferative GN (MPGN) is glomerular injury with increased mesangial matrix, cellularity, and capillary wall thickening. It includes immune-complex MPGN and C3 glomerulopathy. Incidence is rare (1-4 cases per million). Dysregulated complement pathway plays a role. Prognosis is poor, with kidney failure expected within 10 years. Recurrence in transplanted kidney causes graft failure in 50%-90% of recipients.

Case Description: A 59-year-old female presented with lower extremity swelling and fatigue. Vital signs: BP 160/71 mm Hg, PR 65 bpm, RR 16 breaths/min. Lab results: Na-130, BUN-93, Sr.creatinine-3.71, Albumin-3.2. In 2002, she underwent renal transplant due to presumed transitional cell carcinoma of the right kidney with neoplasia in the bladder. Her end-stage renal disease potentially caused by herbal medicine (aristocholic acid) intake. August 2022 biopsy showed glomerular abnormalities: C3c deposits, matrix expansion, sclerosis in 2 out of 5 glomeruli. Cellcept dosage increased to 750mg twice daily, prednisone added. Baseline creatinine 1.0-1.2 mg/dl until 2019, recent value 3.71mg/dl. Worsening proteinuria (urine protein creatinine ratio 1.8g) despite RAAS blockade. Hypertension, chronic hyponatremia, acute anemia (hemoglobin 6.7 g/dl). Anemia treated with packed RBC and IV iron. Repeat biopsy deferred due to bleeding risk from elevated blood urea level. Medication: Cellcept 750mg BID, Cyclosporine 75mg BID, Prednisone 5mg OD. Hemodialysis twice a week, frequency adjusted based on blood urea levels.

Discussion: C3 glomerulopathy recurrence in transplant is not uncommon, but diagnosis of C3 GN on a transplanted kidney who has primary aristocholic acid nephropathy is rare. Diagnosis of C3 glomerulopathy relies on kidney biopsy. C3 predominance of at least two orders of magnitude by IF compared with other immunoreactants has been adopted as a diagnostic criterion. Our patient exhibited similar findings and commenced regular hemodialysis with close monitoring. Hence, native kidney biopsy is crucial in most cases.

Henoch-Schoenlein Purpura (HSP) Nephritis in Adults

Hafiz Sarfraz A. Khan, Irtiza Hasan, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Henoch-Schoenlein purpura (HSP) is a small vessel vasculitis. It affects children more often than adults but renal involvement is more common & severe in adults. Few studies on HSP nephritis (HSN) in adults have been reported. Prompt evaluation & aggressive treatment in HSP nephritis can prevent progression of kidney disease.

Case Description: A 48-year-old non-diabetic, non-hypertensive & non-smoker Caucasian female with PMH of seizure disorder, morbid obesity (BMI 53.8), & asthma, presented with a lower extremity purpuric rash & arthralgia in knees, hip joints. Labs consistent with normal CBC, normal coagulation profile, normal renal function (creatinine 0.77 mg/dl). UA with microscopic hematuria (5 RBCs/HPF) & proteinuria (100 mg/dl). She was suspected to have Henoch-Schoenlein purpura (HSP) based on clinical findings of palpable purpura and arthralgia. Further investigation showed proteinuria of 1904 mg/day & elevated serum IgA level (526 mg/dl). Patient underwent a kidney biopsy that showed mesangial proliferation, mesangial immune complex deposits identified as IgA & C3 on immunofluorescence study and as dense deposits on electron microscopy. These findings were supportive for HSP nephritis. She was started on Lisinopril and prednisone. Repeat urine study showed improvement in proteinuria (189 mg/day) & hematuria (4 RBC/HPF) with 4 months of tapering prednisone therapy.

Discussion: HSP is a small vessel vasculitis. Renal involvement in HSP can cause hematuria, mild-to-moderate proteinuria, RBC cast, elevated serum creatinine, hypertension & nephrotic range proteinuria. Latter 3 presentations are associated with worse renal prognosis. ESRD may develop in 15-25%. Patients with proteinuria >1g/day should undergo kidney biopsy. Adult patients with limited kidney involvement (hematuria, proteinuria <1 g/day, and normal serum creatinine) require no immunosuppressive therapy. ACE inhibitor or ARB is used to reduce proteinuria. Patients with more severe kidney involvement (proteinuria ≥1 g/day, elevated serum creatinine, or crescentic glomerulonephritis on kidney biopsy) require immunosuppressive therapy with glucocorticoids. Our patient had evidence of severe disease (>1g/day proteinuria), therefore she underwent kidney biopsy & required glucocorticoid treatment resulting in almost complete resolution of proteinuria in 4 months. She did not require any further immunosuppressive therapy.

PUB266

Atypical Hypoproteinemia and Fluid Retention: AKI in an IgAκ Multiple Myeloma with Type 2 Diabetes

Shinichiro Koga.[1,2] *[1]Section for Nephrology & Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo, Japan; [2]Department of Diabetes & Endocrinology, Tokyo Hospital, Japan Organization for Occupational Health & Safety, Tokyo, Japan.*

Introduction: Diagnosis of multiple myeloma (MM) is usually evident when chronic bone pain, pathologic fractures, and hypercalcemia are complicated by proteinuria and kidney failure. Cast nephropathy is should be considered when proteinuria (often ≧3 g/day), particularly without concomitant hypoalbuminemia or significant albuminuria, is found in a patient who is ≧ 40 y/o 1).

Case Description: An Asian 75 y/o male had dysarthria as well as right upper limb weakness for 2 weeks. He was brought to ED due to unconsciousness and difficulty of moving by himself, then admitted to the nephrology with pleural effusion, ascites, and

hypoalbuminemia. Past medical history included well-controlled pancreatic diabetes, which basal-bolus insulin regimen was initiated 6 years ago. He had worsen for 6 years to serum Cr 2.33 mg/dL, eGFR 23.3 mL/min/1.73m^2, Alb 1.1 g/dL, TP 4.6 g/dL, Ca 10.4 mg/dL, IgA 645 mg/dL, Hb 8.1 g/dl; urine Alb 59 mg/gCr, TP 270 mg/gCr, and protein 0.2 g/day. Anemia was not improved by transfusions and ESA. Both GIS and CS did not detect active bleeding site, nor amyloid deposition with Congo-Red staining. No Bence Jones protein in urine. Alpha-antitrypsine clearance test excluded malabsorption syndrome. ^{99m}Tc-HSAD scintigraphy excluded protein-losing gastroenteropathy 2). During 2 weeks, he had worsen to Hb 7.7 g/dL, Cr 2.58 mg/dL. Serum free light chain (κ/λ) was 130/152 mg/L (=0.86). SPEP detected IgAκ M protein. Bone marrow show CD79a$^+$ in 30-40 % of eukaryocytes; diagnosed MM IgAκ type. The patient received bortezomib 1.0 mg/m^2/week for 4 weeks with DEX renalidomide. He discharged with no leg edema, UP(+/-), Cr 1.56 mg/dl, eGFR 34.5 ml/min/m^2, TP 6.4 g/dL, Alb 3.0 g/dL, Hb 8.8 g/dL, and IgA 406 mg/dL.

Discussion: It was atypical as main symptoms of MM that the patient had hypoproteinemia and fluid retension instead of acute kidney injury with hypercalcemia. We could not perform kidney biopsy; not confirm presence of cast nephropathy in the patient. Urine protein is within upper limit of normal range, therefore we estimate his acute kidney injury as presenting interstitial nepritis caused by M protein. This case was compatible with incidence that ≧60% reduction of free light chain M protein recovered kidney function in ~80 % case of myeloma kidney 3). Epidemiology of FSGS over a 20-Year Period

Thomas Mcdonnell, Joshua Storrar, Philip A. Kalra, Smeeta Sinha. Donal O'Donoghue Renal Research Centre (DRRC). *Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Manchester, United Kingdom.*

Background: This epidemiological study describes a renal centre's 20 year experience of patients with primary Focal segmental glomerulosclerosis (FSGS), one of the leading causes of nephrotic syndrome (NS) in adults.

Methods: Retrospective longitudinal analysis of primary FSGS at a tertiary renal centre over 2 decades. Baseline demographics, labs and outcomes: Complete (CR) & partial (PR) remission, relapse, progression RRT and mortality were collected.

Results: 87 patients were identified with primary FSGS after exclusion of secondary causes. Mean age was 49.3 years, 60.9% male, 86.2% white with median eGFR 46ml/min, urine PCR 573mg/mmol, serum albumin 33g/l (Table 1). Rates of PR and CR were 23% & 49.4%, respectively. Progression to RRT occurred in 27.4%, death in 27.4%. 29 (33.3%) presented with NS. Those who presented with nephrotic syndrome were more likely to receive immunosuppression (IS) 86.2% vs 20.7% (P<0.001) and more likely to achieve CR 69% vs 39.7% (p 0.01) with no increased rates of relapse. Patients that achieved complete remission were less likely to die; patients that achieved either partial or complete remission were less likely to progress to ESKD (Figure 1).

Conclusions: This Retrospective longitudinal study of primary FSGS over a period of 2 decades provides important prognostic information for this understudied area. Despite the exclusion of secondary causes only 1/3 of patients presented with NS. Those who presented with NS were more likely to receive IS and achieve complete remission. Regardless of whether the patient had NS, complete or partial remission was protective of ESKD and CR was associated with reduced risk of death. Given 27.4% die or progress to RRT, this emphasises the importance of achieving remission, if even partial

Examining the Role of External Factors with Risk of ANCA Vasculitis Relapse

Mary M. Collie,[1] Dhruti P. Chen,[1] Lauren N. Blazek,[1] Yichun Hu,[1] Koyal Jain,[1] Vimal K. Derebail,[1] Nicole Orzechowski,[2] Caroline J. Poulton,[1] Susan L. Hogan,[1] Ronald Falk.[1] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]Division of Rheumatology, Allergy, & Immunology, UNC School of Medicine, Chapel Hill, NC.*

Background: The role of patient-reported stressors, insect bites, and infections on disease relapse of ANCA vasculitis has yet to be well studied.

Methods: In a case-control study of subjects with ANCA vasculitis, we defined cases as those who relapsed (Relapse Cohort) and controls as those who did not relapse (Remission Cohort) during the study (2011-2022). Longitudinal surveys were collected every 3 to 6 months and included self-reported exposures, including stressors (defined as biological, environmental, cognitive, behavioral, and life events), insect bites, and infections. Exposures happening within 15 months before relapse were included in the Relapse Cohort, and exposures happening in the 15 months after achieving remission were included in the Remission Cohort. The two groups were compared using Fisher Exact, Wilcoxon 2-sample, and Cochran-Armitage Trend tests.

Results: The number of reported infections (Table) was higher in the Relapse Cohort than in the Remission Cohort (p=0.03). Upper respiratory infections were most common, and consistently reported more frequently between 6 and 15 months before relapse versus 15 months post-remission (p-trend=0.0017, Figure). There was no significant evidence for stressors and insect bites as external factors in disease relapse.

Conclusions: More frequent patient-reported infections, specifically upper respiratory infections, may contribute to patient vulnerability to relapse for up to 15 months after infection. Counseling and closely monitoring patients after infectious symptoms could aid in earlier detection of disease flares.

IgA Nephropathy and Thrombotic Microangiopathy: A Rare Manifestation of Lupus After COVID-19 Infection

Kelly V. Liang, Kimberly P. Liang, Timothy A. Fields. *University of Kansas School of Medicine, Kansas City, KS.*

Introduction: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease which may present with lupus nephritis (LN), lupus anticoagulant (LAC) and thrombotic microangiopathy (TMA). SLE is rarely described in association with non-lupus glomerulonephritis (GN). We present a case of SLE presenting with renal dysfunction, hypertension (HTN), proteinuria, and microscopic hematuria in a patient with LAC, shortly after COVID-19 infection, in which renal biopsy confirmed IgA nephropathy (IgAN) with TMA.

Case Description: A 37-year-old male with history of antiphospholipid syndrome (APLS) with LAC, right leg deep vein thrombosis in 2016, osteosarcoma of left distal femur in 2002, melanoma in 2022, HTN, and hyperlipidemia, was referred to Nephrology in December 2022 for elevated creatinine (Cr) and proteinuria. In September 2022, he developed right leg numbness/tingling and facial droop. He caught COVID-19 in late November 2022. In December 2022, he presented with severe HTN (SBP>200), Cr 1.6-1.7 mg/dL, urine protein/Cr ratio (UPCR) 7000 mg/g Cr, microscopic hematuria, low-normal C3, low C4, +ANA (1:1280), +dsDNA Ab, negative anti-GBM Ab, normal SPEP, and negative hepatitis. He was treated with methylprednisolone 500 mg IV daily x 3 days. Renal biopsy in late December 2022 revealed IgAN (Oxford Class M1 E1 S0 T0 C0) with concomitant TMA. After steroid therapy, his eGFR improved from 49 to 54 mL/min, Cr improved from 1.7 to 1.4 mg/dL, and proteinuria improved from 7000 to 3000 mg/g Cr in early January 2023. He was initiated on losartan, amlodipine, fish oil, atorvastatin, and hydroxychloroquine (HCQ). In February 2023, a rheumatologist diagnosed him with SLE. In April 2023, his UPCR improved to 300 mg/g Cr and Cr was stable.

Discussion: This is a rare case of SLE presenting with renal dysfunction, HTN, proteinuria, and microscopic hematuria found to be due to IgAN rather than LN, in conjunction with TMA in the setting of LAC. It underscores the importance of performing renal biopsy in patients suspected of having LN, as other GN's may coexist with SLE. This case is unique in that the onset of IgAN and SLE occurred after COVID-19 infection, which may increase risk of autoimmune disorders. Clinical response was like that of non-SLE associated IgAN. This case supports the utility of HCQ as a therapeutic option in IgAN, particularly in IgAN occurring in SLE.

PUB270

Use of Mycophenolate Mofetil (MMF) in IgA Nephropathy: When Steroids Induce Psychosis

Farhana Begum, Daniel W. Ross, Deepa A. Malieckal. *Northwell Health, New Hyde Park, NY.*

Introduction: IgA nephropathy (IgAN) is one of the most common glomerular diseases worldwide and up to 40 % can progress to ESKD. Current management of IgAN is focused on supportive care (SC), to slow the rate of progression. This includes BP management, low Na diet, ACE/ARB use if proteinuria >500mg/d, weight loss, exercise, smoking cessation, and CV optimization. KDIGO currently recommends that patients who remain at high risk of progressive CKD despite maximal SC, be considered for a 6-month course of glucocorticoid therapy.

Case Description: 66F history of SLE, HTN, HLD, depression presented to hospital with fatigue and anemia seen on outpatient labs, found to have symptomatic anemia (Hgb 5.8) requiring 2u pRBCs and complicated by AKI. Patient underwent EGD, which was normal and Hgb remained stable, so was placed on PPI and advised against NSAID use. On admission the patient's serum creatinine (SCr) was noted to be 3.49 mg/dL with gross hematuria and spot urine total protein/creatinine ratio of 2.4g. Baseline SCr was 1.0 three months prior, increased to 2.2 one month prior. A kidney biopsy was performed but was an inadequate sample. She was started on empiric steroid therapy for concern for RPGN, however had steroid induced psychosis and steroids were stopped. Patient was discharged with SCr of 2.73 and underwent repeat biopsy outpatient which showed focal proliferative IgAN with cellular crescents in 20 % of glomeruli, and moderate acute interstitial nephritis. Given patient's contraindication to steroids, she was started on MMF with stable kidney function and improving proteinuria (SCr 1.46 and urine protein/Cr ratio 0.7).

Discussion: The appropriate therapy for IgAN with crescents and proteinuria remains uncertain. The TESTING study showed use of steroids reduced kidney failure, however it increased serious adverse events (AE). Steroids were not well studied in patients with eGFR< 50 and not every patient can tolerate steroids. There has been mixed data regarding the use of MMF as a steroid sparing agent. MMF may be a reasonable alternative to reduce progression of IgA nephropathy.

MMF use in IgA Nephropathy

Date	Authors	Findings
2/2023	Hou FF, Xie D, Wang J, et al.	MMF reduced progression of CKD compared to SC
2/2017	Hou JH, Le WB, Chen N, et al.	MMF + steroids vs steroids did not reduce proteinuria but had less AEs
11/2015	Hogg RJ et al.	MMF had no change in proteinuria compared to placebo

Clinical Characteristics, Histologic Patterns, and Disease Outcomes in C1q Nephropathy (C1qN): A Single-Center Experience

Zachary S. Bruss,[1] Saeed K. Shaffi,[2,1] Brent Wagner.[2,1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G. Murphy VA Medical Center, Albuquerque, NM.*

Background: C1qN is a rare glomerulopathy associated with mesangial dominant C1q deposition on immunofluorescence staining. Clinical presentation and outcomes are heterogenous, ranging from asymptomatic proteinuria to nephrotic syndrome. We explore the demographic and clinical characteristics of a C1qN cohort stratified on nephrotic syndrome at diagnosis.

Methods: We searched the University of New Mexico Kidney Biopsy registry for instances of C1qN. We excluded transplant recipients, obtained the relevant demographic and clinical data from the electronic medical records, and summarized and compared data stratified on nephrotic syndrome at diagnosis.

Results: Of the 11 renal biopsies with C1qN, 8 were native and were included in this study. Patients with nephrotic syndrome were younger, had higher proteinuria and serum cholesterol, and lower albumin (table 1). Patients without nephrotic syndrome had greater microscopic hematuria. Apart from a greater degree of foot process effacement in patients with nephrotic syndrome, no other trends were evident on microscopy. Patients with nephrotic syndrome were likely to receive immunosuppressive therapy. Disease relapse was seen often in patients with nephrotic syndrome; however, immunosuppressive therapy led to proteinuria resolution in all patients.

Conclusions: C1qN is an immune-complex mediated rare diagnosis afflicting children. Nephrotic syndrome is associated with foot process effacement and a trend towards frequent relapses. Patients without nephrotic syndrome have microscopic hematuria and are less likely to relapse. Therefore, patients with C1qN - especially those with nephrotic syndrome at diagnosis - should have a long-term follow-up to identify disease relapse.

Atypical Anti-Glomerular Basement Membrane Disease with IgA Nephropathy: A Rare Dual Pathology in Rapidly Progressive Glomerulonephritis

Malinporn Jampong,[1,2] Boonyarit Cheunsuchon,[2] Nuttawut Rongkiettechakorn,[1,2] Manoch Rattanasompattikul.[1,2] *[1]Golden Jubilee Medical Center, Nakorn Pathom, Thailand; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Introduction: The anti-GBM disease is a rare small vessel vasculitis in which circulating antibodies are directed against an antigen intrinsic to the glomerular basement membrane (GBM) and/or alveolar basement membrane, resulting in rapidly progressive glomerulonephritis and/or alveolar hemorrhaging. A diagnosis of anti-GBM was obtained based on the identification of anti-GBM antibodies, either in serum or in tissue, along with pathological features of crescentic glomerulonephritis with or without evidence of alveolar hemorrhaging. The authors describe one such case with a dual pathology involving IgA nephropathy and atypical anti-GBM disease.

Case Description: A 48-year-old female with microscopic hematuria and proteinuria in the nephrotic range accompanied by a slight elevation in serum creatinine presented to our facility. The pathological results of a renal biopsy showed a crescentic glomerulonephritis and an immunofluorescence pattern, indicative of a dual pathology of IgA nephropathy and anti-GBM disease (Figure 1). Serum anti-GBM antibody titer was not detected. After treatment with pulse methylprednisolone, 10 plasma exchange therapy

sessions over two weeks, and oral cyclophosphamide, the patient's serum creatinine returned to relatively stable levels, and her hematuria and proteinuria improved over the subsequent six months.

Discussion: Atypical anti-GBM disease manifests milder kidney injury and minimal pulmonary hemorrhaging compared to classical cases. In this case, the patient's condition improved, and renal function remained relatively stable with corticosteroid, plasma exchange therapy, and oral cyclophosphamide treatment.

Experience with Ravulizumab in Atypical Hemolytic Uremic Syndrome

Víctor J. Escudero-Saiz,[1] Marta Martínez-Chillarón,[1] Elena Guillen,[1] Alicia M. Andújar,[1] Marc Xipell Font,[1] Carla Bastida,[2] Gastón J. Piñeiro,[1] Esteban Poch,[1] Luis F. Quintana,[1] Josep Miquel Blasco Pelicano.[1] *[1]Hospital Clinic de Barcelona Servei de Nefrologia i Trasplantament Renal, Barcelona, Spain; [2]Hospital Clinic de Barcelona, Barcelona, Spain.*

Background: The arrival of eculizumab revolutionized the treatment of Atypical Hemolytic Uremic Syndrome (aHUS). Ravulizumab also offers C5 inhibition but with longer half-life. We describe the experience with ravulizumab in two scenarios: switching from another C5 inhibitor in stable patients and direct therapy initiation (naïve).

Methods: We present 9 patients with 42±13years and 81±12.4kg. Switching to ravulizumab began 2 weeks after the last eculizumab dose while in naïve patients it started after excluding other causes of aHUS. Initial dose was 2700mg followed by 3300mg after 2 weeks and subsequently every 2 months. Analytical variables of renal function, hematological and complement parameters were collected.

Results: *Switch*: 6 patients (50%females), 4/6 transplant recipients (3 on prophylactic treatment). Regarding renal function, 5/6 had complete response with eculizumab (creatinine 1.33±0.32mg/dL, eGFR 59.5±34.3mL/min/1.73m2, proteinuria 115±91.5mg/g), and all had complete hematological response. After the switch, all maintained complete hematological response, renal function stability and serum complement levels. *Naïve*: 3 cases (2 males); 2/3 required hemodialysis (HD) at presentation. Renal response was complete in two patients and partial in the third (who discontinued HD after 90 days and currently remains with CKD-G3b). All had complete hematological response. Only 3 adverse effects were documented (arthralgia, headache, and rhinitis), no infection cases.

Conclusions: Ravulizumab use is effective both maintaining complete response after switching from eculizumab and as first-line therapy. The safety profile is comparable with the main difference being the posology, as ravulizumab requires fewer administrations and leads to a reduction in direct and indirect costs.

Anti-Phospholipase A2 Receptor (Anti-PLA2R) Antibody in Diagnosis and Treatment of Idiopathic Membranous Nephropathy: A Single-Center Experience

Muhammad Sajid R. Abbasi,[1] Rukhsana Manzoor,[2] Khawar Sultan.[1] *[1]Pakistan Institute of Medical Sciences, Islamabad, Pakistan; [2]East Kent Hospitals University NHS Foundation Trust, Canterbury, United Kingdom.*

Background: The aim of this study was to observe the prevalence of serum Anti-Phospholipase A2 Receptor (Anti-PLA2R) in patients with idiopathic membranous nephropathy (IMN) and to observe its clinical and laboratory parameters in Pakistani population.

Methods: We enrolled 84 patients with idiopathic membranous nephropathy who were diagnosed on renal biopsy. Study group had nephrotic syndrome at the time of presentation. These patients further had testing for serum anti-PLA2R antibody, serum albumin, 24 hour urinary protein (24 U/P), serum creatinine and GFR estimation. Serum anti-PLA2R antibody was measured by enzyme-linked immunosorbent assay (ELISA). These patients were treated with combination therapy of low dose steroids and CNI(tacrolimus,CSA) and response was assessed at 6 months.

Results: Thirty seven 37 (44%) patients were positive for serum anti-PLA2R antibody while Forty seven 47 (55%) patients were negative among all patients with iMN. Patients who were positive for serum serum anti-PLA2R antibody had high level of 24 urinary protein, low level of serum albumin at the time of presentation in comparison with those who were negative for serum anti-PLA2R antibody (p : 0.05). In terms of response to treatment, in patients with serum anti-PLA2R antibody positive, at 6 months complete and partial repose was 38% and 45% respectively. In anti-PLA2R antibody negative group at 6 months complete and partial repose was 62% and 20% respectively.

Conclusions: Serum anti-PLA2R antibody is non-invasive technique, clinically helpful and specific biomarker for diagnosis of IMN. Our results suggest that serum anti-PLA2R antibody can help to diagnose, predict course of disease and response to therapy in IMN patients.

A Case of Severe Parvovirus B19 Infection with Glomerulonephritis Requiring Artificial Ventilation

Daisuke Matsui, Daiki Aomura, Takayuki Nimura, Kosuke Yamaka, Koji Hashimoto, Yuji Kamijo. *Shinshu Daigaku Igakubu Fuzoku Byoin, Matsumoto, Japan.*

Introduction: Initial infection of parvovirus B19 (PVB19) is known to occasionally cause inflammation in systemic organ tissues such as myocarditis and glomerulonephritis (GN), and possibly result in severe outcomes including death. In the present case, we encountered a patient with severe PVB19 infection along with GN, requiring artificial ventilation.

Case Description: A 22-year-old female developed a fever along with rashes on her extremities. Antibiotic therapy was initiated at a previous hospital, with less effectiveness. One month later, she also complained about dyspnea and was referred to our hospital. She had no past history and had taken no medicines before the onset of her symptoms. Her blood pressure and heart rate were 127/105 mmHg and 94 /min, respectively. Her respiratory rate was 31 /min and required 4 L/min of oxygen. Chest CT revealed findings of severe pulmonary edema, and ultrasound cardiography found diffuse left ventricular hypokinesis as well. Due to her severe respiratory failure, artificial ventilation was initiated. Blood and urine tests at the admission found an increase in serum level of creatinine (1.1 mg/dL) and C-reactive protein (4.9 mg/dL), and the presence of glomerular hematuria and proteinuria (1.1 g/gCr). These findings indicated the involvement of GN-related diseases; therefore, a kidney biopsy was performed under artificial ventilation to aid in the diagnosis. It revealed the pathological findings of infection-related GN and following serum examination found the high titer of an IgM antibody for PVB19. Intravenous injection of methyl prednisone (1000 mg/day for 3 consecutive days) dramatically improved her respiratory failure and urine findings, and she was discharged without any sequelae. With these clinical presentations, we diagnosed her as having severe PVB19 infection accompanied by GN.

Discussion: PVB19 infection can be fatal due to the inflammation mediated by globoside, a receptor for PVB19 expressed in the heart, lung, and kidney. However, since the initial symptoms of PVB19 are complicated and present with various manifestations, it is difficult to detect systemic injury caused by PVB19 infection at an early stage. For patients who have systemic organ injuries with abnormal urine findings, PVB19 infection should be suspected, and a kidney biopsy needs to be taken into account.

PUB276

Immunoglobulin A Nephropathy Management Quality Improvement Initiative Project in China

Gengru Jiang, Fujun F. Lin. Committee of Quality Improvement Initiative Project in China. *Renal Division, Department of Internal Medicine, Xin Hua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*.

Background: In China, Immunoglobulin A nephropathy (IgAN) accounts for 45%-53% of biopsy-confirmed primary glomerulonephritis and individuals of Pacific Asian origin are 1.56 times more likely to develop end-stage renal disease compared with other origins. Currently, there is few nationwide data on the diagnosis and treatment patterns of IgAN in China. Immunoglobulin A Nephropathy Management Quality Improvement Initiative Project in China (IGAN-MIC) aims to establish an IgAN cohort collaboration network to learn about the real-world practice of IgAN management in China.

Methods: IGAN-MIC project will establish an IgAN Chinese expert committee consisting of 14 experts from 13 regions in China with geographical representativeness to assess differences between regions and ethnicities. These hospitals play leading roles in the nephrology development in their provinces and nearby areas. The first-stage of IGAN-MIC project is to establish a nationwide data platform to extract data on clinical characteristics, renal biopsies, diagnosis, comorbidities, laboratory results and medications from electronic medical records and hospital information systems. Biopsy date will be defined as the index date and follow-up data will also be recorded. The second-stage of the project focuses on physician education activities via presentations and handbooks based on the management gap on the data platform.

Results: IGAN-MIC is designed to focus on the pathologic classification, prognostic assessment, medication used and improvement of key laboratory results after IgAN management. The project is scheduled to start in July 2023 and end by December 2024. All hospitals with capabilities of performing renal biopsy and IgAN treatment can join the network. Over 100 healthcare institutions in China are expected to participate with a minimum of 5000 IgAN patients enrolled to develop a portrait of IgAN diagnosis and treatment in China, also to fill the gap in this area globally.

Conclusions: IgAN is the most common glomerular disease in China. The IGAN-MIC project aims to optimize the management of IgAN in China.

PUB277

Late-Onset Lupus Nephritis Presenting as Acute Decompensated Heart Failure

Alina Cheema,[1] Soo Hyun Kae,[3] Matthew Min,[1] Sankar N. Niranjan.[2] *[1]UConn Health, Farmington, CT; [2]Greater Hartford Nephrology, Bloomfield, CT; [3]Trinity Health of New England, Hartford, CT*.

Introduction: Lupus nephritis (LN) occurs in 20-50% of systemic lupus erythematosus (SLE) cases and usually develops within the first 5 years of SLE diagnosis, rarely occurring afterward. We describe a case of late-onset LN in a patient with known SLE who presented with acute systolic heart failure.

Case Description: A 64-year-old female with a history of SLE for 31 years without renal involvement, atrial fibrillation, prior right innominate artery occlusion, hypertension and type 2 diabetes presented to the hospital with worsening exertional shortness of breath. Physical exam was notable for stable vitals, bibasilar rales on lung auscultation and 3+ bilateral lower extremity pitting edema. Laboratory investigation was significant for serum creatinine (SCr) 2.9 mg/dL, with a baseline of 0.9-1.1 mg/dL, BUN 27 mg/dL, albumin 1.8 g/dL and BNP 110 pg/mL. Echocardiogram revealed a mildly reduced ejection fraction of 40-50% with a small pericardial effusion and a chest x-ray showed vascular congestion and a left pleural effusion. He was admitted for acute systolic heart failure and acute kidney injury. Further workup revealed a urine protein/creatinine ratio of 16.01. C3 and C4 complement levels were within normal range. Given the nephrotic-range proteinuria, the patient underwent a kidney biopsy which showed class V membranous nephropathy and acute tubular necrosis, consistent with LN. Along with diuresis, the patient was initiated on mycophenolate mofetil 1000 mg twice daily and pulse doses of IV methylprednisolone with taper. On discharge, SCr improved to 1.3 mg/dL and the patient had close follow-up for management of the newly diagnosed LN.

Discussion: This is a unique case of late-onset LN occurring 31 years after SLE diagnosis. The patient's chronic SLE symptoms of malar rash, fatigue and joint pain were managed with prednisone and hydroxychloroquine up until this presentation of acute systolic heart failure. There are few reported cases in literature of LN occurring 30 years after SLE diagnosis. With the increasing lifespan due to effective treatment options for SLE, late-onset LN may become more prevalent. As such, we recommend that physicians closely monitor signs and symptoms of LN even in patients without initial renal involvement.

PUB278

Hydralazine-Induced Vasculitis: A Case Report

Jacob Scribner, Kumail Ali, Oladapo O. Afolabi, Isha Puri. *Texas Health Resources Foundation, Fort Worth, TX*.

Introduction: Hydralazine-induced ANCA-Associated Vasculitis (AAV) is a rare condition in which there is an autoimmune mediated reaction leading to renal and pulmonary involvement and complications.

Case Description: A 37-year-old female with a history of hypertension, hyperlipidemia, DVTs, and multiple strokes who presented for anemia and elevated creatinine. Home medications consisted of Lipitor, Coreg, Xarelto, and Hydralazine. After admission, the patient developed fevers and orbital swelling. Hydralazine was stopped due to concerns of association with her periorbital edema. The patient was started on antibiotics for suspected orbital cellulitis. CT imaging showed a large pericardial effusion, as well as multiple pulmonary nodules. ECHO showed cardiac tamponade. The patient had an emergent pericardial window. Autoimmune workup for pericardial effusion and pulmonary nodules was started. The patient was found to be ANA, p-ANCA positive (MPO and PR3). The patient was worked up for ANCA vasculitis. Further testing revealed high levels of dsDNA and anti-histone antibodies. Renal biopsy was deferred in the setting of anticoagulation use. She was started on high dose steroids and discharged with improved renal indices.

Discussion: Hydralazine is a common anti-hypertensive medication. It is known to cause drug induced Lupus (DIL), but it is less commonly associated with ANCA-Associated Vasculitis (AAV). AAV has a predilection for renal and pulmonary vasculature. Inflammation is caused by autoantibodies against myeloperoxidase (MPO) and Proteinase 3 (PR3). Renal biopsy demonstrates pauci-immune glomerulonephritis. Hydralazine-induced AAV is dose and duration dependent. Risk factors include female gender, kidney disease, and old age. Complications of AAV include rapidly progressive glomerulonephritis, as well as pulmonary-renal syndrome. The incidence of Hydralazine-induced AAV is about 10-20 cases per million. Treatment consists of drug cessation and immune modulator therapy. It can be challenging to differentiate between DIL and Hydralazine-induced AAV. Anti-histone antibody positivity and hypocomplementemia are not independent between the two. DIL lacks antibodies to dsDNA, and ANCA levels are not elevated in DIL; ANCA positivity is diagnostic of AAV. Hydralazine-induced AAV can be challenging to recognize and diagnose. Immediate cessation of Hydralazine and prompt initiation of immune modulators mainstay treatment.

PUB279

Kicking a Glomerulus When It's Already Down

Russell Davis, Alan Segal. *Maine Medical Center, Portland, ME*.

Introduction: Hydralazine-associated ANCA vasculitis (HA-AV) can be a devastating complication, with a pathogenesis that is not well understood. Here, we present a patient with biopsy-proven membranous glomerulopathy and IgA nephropathy who developed HA-AV.

Case Description: A 74-year-old man with CKD IV from biopsy proven membranous glomerulopathy (negative PLA2R and THSD7A) and mild concurrent IgA nephropathy was transferred to our institution with acute kidney injury and acute hypoxemic respiratory failure. The prior biopsy also demonstrated severe interstitial fibrosis and tubular atrophy. CT Chest revealed extensive multifocal airspace disease in both lung fields. Bronchoscopy with bronchoalveolar lavage confirmed diffuse pulmonary hemorrhage with bloody aliquots. Hydralazine for hypertension was discontinued. Pulse dose steroid treatment was initiated along with apheresis. Initial work-up returned as follows: ANA titer 1:160, MPO-ANCA titer 990, normal complements, infectious workup negative, Anti-ds-DNA, SS-A, and SS-B antibodies were negative. Patient received IV Cytoxan once and was begun on Rituximab therapy with improvement in respiratory symptoms. Kidney function worsened requiring dialysis briefly with improvement to baseline kidney function.

Discussion: HA-AV can be a long-term complication of hydralazine treatment and can be quite serious. In this case, the patient was treated by discontinuing the medication. Due to the severity of this patient presentation, apheresis, pulse dose steroids, Cytoxan, and Rituximab therapy were utilized. Of the known risk factors, the patient did have a history of hypothyroidism. Hydralazine also was dosed in a range consistent with most cases on literature review that would put him at risk for developing hydralazine induced MPO ANCA. The patient did not undergo further kidney biopsy due to the degree of advanced kidney disease seen on imaging and previous biopsy. The patient responded well to treatment and was discharged after several weeks to rehab with close follow-up. The patient did quite well for many months. Subsequent medical complications after a cardiovascular procedure have led to progression of his renal disease and transition to ESRD on hemodialysis. We conclude that, given numerous anti-hypertensive alternatives, hydralazine should be avoided if at all possible, and if not, the duration of treatment should not be prolonged.

PUB280

A Rare Case of Anti-PLA2R-Negative Membranous Nephropathy and ANCA-Negative Crescentic Glomerulonephritis

Chavely Valdes Sanchez, Ryan LaMarca, Yiqin Zuo, Marie A. Sosa. *University of Miami Hospital and Clinics, University of Miami Health System, Miami, FL, US, health/system, Miami, FL*.

Introduction: It is reported that the sensitivity of PLA2R staining is 75% and specificity is 83%, for the detection of primary membranous nephropathy (MN); therefore, negative anti-PLA2R does not exclude primary MN. Also, it has been reported

that 10-30% of patients with pauci-immune crescentic glomerulonephritis (GN) are ANCA-negative. Here we have a case of combined PLA2R negative MN and ANCA negative pauci immune crescentic GN.

Case Description: A 59 year old man with a medical history of hypertension, chronic kidney disease stage 3A, and history of treated syphilis presents with shortness of breath, admitted for community acquired pneumonia management. Patient also diagnosed with an acute kidney injury. Labs showed serum creatine at 3.56, urinalysis with proteinuria (1g) and 2-5 RBC. Immunological studies showed positive SM/RNP antibody (ab) but negative Smith ab, ds-DNA ab, ANCA panel, anti-PLA2R ab, glomerular basement membrane (GBM) ab, and normal c3/c4. Infectious work-up showed positive RPR, negative quantiferon, negative hepatitis B surface ab and negative hepatitis C ab. Renal biopsy showed PLA2R antibody negative MN, pauci immune crescentic GN, and acute tubular injury.

Discussion: Our patient presents with findings that suggest an overlap of primary membranous nephropathy and pauci-immune crescentic GN. By renal biopsy, characteristic findings of primary MN such as fine spikes and holes along the GBM are present but PLA2R staining is negative. As well, three glomeruli show cellular crescents and additional fibrocellular and fibrous crescents were identified, and these findings are unusual in primary MN. A secondary MN is also unlikely in view of no endocapillary hypercellularity. Given lack of linear GBM staining and no autoimmune symptoms, the crescentic lesions can be suggestive of a pauci-immune mediated process, however, the patient had negative ANCA serologies checked twice. A recent study showed ANCA-negative pauci-immune crescent glomerulonephritis can be primary or secondary, especially if associated with infection or malignancy that requires prompt identification and specific treatments. It is important to realize that association of vasculitic GN with MN is estimated to be <5% of all membranous GN cases, thus this case can be used as future reference for clinical practice.

PUB281

The Utility of Kidney Biopsy in PLA2R-Positive Membranous Nephropathy

Michael Chau,[1] Vinay Srinivasan,[1,2] Sameena Khan,[1,2] Solomon Dawson.[1,2]
[1]Cooper University Health Care, Camden, NJ; [2]Rowan University Cooper Medical School, Camden, NJ.

Introduction: Primary membranous nephropathy (MN) is one of the major causes of nephrotic syndrome. In the last decade, studies have shown that anti-phospholipid A2 receptor (PLA2R) antibodies are positive in 70% to 80% of patients with a high specificity for MN. Traditionally, the diagnosis was made through kidney biopsy; however, testing for serum PLA2R antibodies has introduced the possibility of diagnosing patients non-invasively. We describe a case of MN that was complicated by a rapid decline in kidney function and discuss the value in obtaining a kidney biopsy even in the setting of a high serum PLA2R titer.

Case Description: A 67-year-old woman with a history of Type 2 DM and HTN presented due to a 20-pound weight gain and worsening dyspnea; exam was notable for 2+ bilateral lower extremity edema. Objective data showed a serum creatinine of 1.46 mg/dL (~1.0 mg/dL 3 months prior), 24-hour urine protein of 16.7 g/day, and a serum albumin of 2.0 g/dL. Immunologic testing showed an anti-PLA2R titer of 455 RU/mL, positive ANA in > 1:1280 titer, anti-dsDNA < 1 IU/mL, and normal complements levels. She was diuresed for her nephrotic syndrome and continued maximally tolerated Losartan. She was treated using a low dose Prednisone, Cyclophosphamide, and Rituximab regimen. However, her kidney function declined further prompting kidney biopsy 2 weeks after presentation. Serum creatinine at time of biopsy was 2.53 mg/dL. Her biopsy showed MN, diffuse and focal nodular diabetic glomerulosclerosis, moderate (20-30%) interstitial fibrosis and tubular atrophy, and severe arteriosclerosis. Her MN alone did not account for the significant decline in GFR and Losartan was discontinued due to concern for hypoperfusion in the setting of renin-angiotensin-aldosterone system blockade with underlying severe arteriosclerosis. Her course was complicated by severe cytopenias resulting in cessation of immunosuppression and she ultimately required dialysis.

Discussion: Although there are many cases of PLA2R positive MN where biopsy can be deferred, it was vital in revealing a secondary diagnosis of severe arteriosclerosis explaining her GFR decline and guiding decision making in our case. Even in the setting of high anti-PLA2R antibody titers, biopsy should be strongly considered for patients with declining kidney function to elucidate whether the decline is secondary to underlying MN or another etiology.

PUB282

Crescentic Glomerulonephritis in Immunoglobulin A-Associated Vasculitis Without Purpura in an Adult Patient

Caroline F. Carrera, Ricardo M. Borges, Washington A. Freire Filho, Felipe Carvalho Barros Sousa, Liliana M. Kassar, Livia B. Cavalcante, Lectícia Jorge, Cristiane B. Dias, Luis Yu. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Introduction: Immunoglobulin A (IgA) vasculitis, formerly called Henoch–Schönlein purpura, is a systemic, immune complex–mediated vasculitis affecting small vessels with dominant IgA deposits. Although rare in adults, it tends to be more severe than in children and is defined by a tetrad of clinical features: palpable purpura (leukocytoclastic vasculitis), arthralgia and/or arthritis, abdominal pain and kidney disease. Specific therapies are still controversial and their efficacy poorly known.

Case Description: A 35-year-old healthy male patient with a history of an isolated episode of macroscopic hematuria pending investigation was admitted at our service a few days after a low-intensity trauma, followed by unilateral visual loss. Brain MRI showed intraluminal thrombosis in the right internal carotid artery, not entirely compatilble with the trauma mechanism. On admission, acute kidney injury, hypertension, microscopic hematuria, subnephrotic proteinuria, bicytopenia, and daily fever were noted. Acute phase markers were elevated and viral serologies, ANCA, Anti-MPO, Anti-PR3, rheumatoid factor were negative. C3 and C4 were normal. Kidney biopsy showed IgA deposition with mesangial hypercellularity, focal crescents and podocyte hypertrophy/hyperplasia. Abdomen AngioCT showed parietal calcifications at infrarenal abdominal aorta and coronary arteries, suggesting the diagnosis of systemic vasculitis. Methylprednisolone and cyclophosphamide were initiated.

Discussion: Purpura has been postulated as a mandatory clinical criterion for IgA vasculitis diagnosis. In this case report, the patient presents with systemic, radiological and anatomopathological renal signs compatible with IgA vasculitis, lacking the typical purpura.

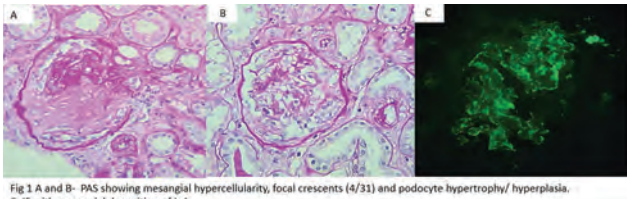

Fig 1 A and B- PAS showing mesangial hypercellularity, focal crescents (4/31) and podocyte hypertrophy/ hyperplasia. C: IF with mesangial deposition of IgA.

PUB283

Can Serum and Histologic Biomarkers Predict Kidney and Overall Survival in ANCA-Associated Vasculitis?

António Inácio,[1] Ana D. Piedade,[1] Patrícia A. Domingues,[1] Beatriz B. Mendes,[1] Liliana Cunha,[1] Karina Soto.[1,2] *[1]Centro Hospitalar de Setubal EPE, Setubal, Portugal; [2]iNOVA4Health, Oeiras, Portugal.*

Background: ANCA vasculitis (AAV) still have poor renal and overall survival. The role of prognostic factors is yet to be defined. Herein, we explored serum and pathological biomarkers as predictors of kidney and patient survival.

Methods: Retrospective analysis of AAV glomerulonephritis diagnosed between 2006-2023 was performed. Most significant markers as ANCA titer, C3 and CRP at admission (d), remission, relapse, and last follow-up (f) were associated to GFR, dialysis need, ESKD and mortality. Berden classes (BC), Brix renal risk score (BRS), IFTA and crescentic glomeruli percentages, C3-IF and interstitial hemorrhage (IH) were also associated with outcomes.

Results: A total of 62 patients 69±10 years old, 56,5% male and 82,3% MPO were included; in 46 biopsies 17.4% were sclerotic, 28.3% mixed, 39.1% crescentic, 15.2% focal; 2.2% with low, 28.3% medium and 58.7% high ESKD risk. dANCA didn't relate to dialysis requirement and titers didn't relate to GFR at any time point. fC3 predicted ESKD (p=0.028) and shorter time to dialysis (p=0.006), not confirmed by multivariate analysis (MA). Likewise, dCRP related to dialysis need (p=0.035) only in univariate analysis. ANCA titers didn't predict survival. dANCA did not relate to death. Lower dC3 (p=0.023) and higher fCRP (p=0.012) were markers of mortality. MA with age and gender lost dC3 significance for death. fCRP seems to remain significant (p=0,06, model p=0,05). C3, CRP and dANCA didn't relate to any histological variable. Higher fANCA predicted higher BRS (p=0.037), persisting on MA (p<0.001, model p<0.001). IH was an independent predictor of ESKD in a MA with gender, age, GFR and dialysis need at admission (HR 0.332, CI 0.114-0.968, p=0.043; model p=0.002). BC didn't predict ESKD. IFTA, BC and BRS didn't predict mortality.

Conclusions: In our cohort, serum biomarkers value remains uncertain. Higher ANCA at last follow-up related to ESKD and histologic chronicity. Nonetheless, didn't predict kidney survival. Last-CRP relation to death might translate infectious bias, although not analyzed. Initial C3 might be prognostic, in line with C3 deposition in other studies, but C3 deposition didn't predict ESKD. IH might be relevant in future broader studies. Further and larger studies might bring stronger data and we still need better predictive markers.

PUB284

Associations of sTNFR-1, sTNFR-2, and YKL-40 with Histopathologic Lesions in Individuals with Glomerular Disease

Insa M. Schmidt,[1] Sophie E. Claudel,[1] Ashish Verma,[1] Courtney Huynh,[1] Ragnar Palsson,[4] Isaac E. Stillman,[2] Anand Srivastava,[3] Sushrut S. Waikar.[1]
[1]Boston University, Boston, MA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]University of Illinois Chicago, Chicago, IL; [4]Massachusetts General Hospital, Boston, MA.

Background: Soluble tumor necrosis factor-1 (sTNFR-1), sTNFR-2, and YKL-40 may provide non-invasive assessments of histopathology, but there is limited data on their associations with histopathologic lesions in individuals with glomerulopathies.

Methods: We measured each plasma biomarker in 188 plasma samples from individuals with glomerulopathies, enrolled into the Boston Kidney Biopsy Cohort (BKBC), a cohort of individuals with semi-quantitative assessment of histopathologic lesions from clinically indicated native kidney biopsies. Multivariable linear regression models tested associations between biomarkers and histopathologic lesions in subgroups of individuals with glomerulopathies, including IgA nephropathy, systemic lupus erythematosus with lupus nephritis (SLE), membranous nephropathy (MN), and secondary focal segmental glomerulosclerosis (sec FSGS).

Results: The mean baseline eGFR was 70±35 ml/min/1.73m² and median proteinuria [IQR] was 1.8 [0.7, 3.7] g/g creatinine. Twenty-eight % of individuals with glomerulopathies had IgA nephropathy, 36% had SLE with lupus nephritis, 20% had MN, and 16% had sec FSGS. After multivariable adjustment for age, race, sex, and eGFR, higher plasma sTNFR-1 levels were associated with more severe mesangial expansion (beta=1.58, p=0.027) in individuals with IgA nephropathy. In individuals with SLE, higher sTNFR-2 levels were associated with the presence of inflammation in the non-fibrosed interstitium (beta=0.76, p=0.019) and lower levels of sTNFR-1 were associated with the presence of inflammation in the fibrosed interstitium (beta=-0.90, p=0.034). Higher levels of plasma YKL-40 associated with more severe arteriolar sclerosis (beta=0.87, p=0.028) in individuals with MN. There were no significant associations between biomarkers and histopathologic lesions in individuals with sec FSGS (**Figure 1**).

Conclusions: Plasma sTNFR-1, sTNFR-2, and YKL-40 may aid with the non-invasive assessment of histopathologic patterns of injury in individuals with IgA nephropathy, SLE with lupus nephritis, and MN.

PUB285

Prevalence and Trend of Biopsy-Proven IgA Nephropathy in China: A Systematic Review

Lichen Xu, Guisen Li. *Department of Nephrology and Nephrology Institute, Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: IgA nephropathy (IgAN) is one of the most common primary glomerulonephritis worldwide, and its distribution varies significantly in different regions. The prevalence and trend in different regions of China remains unclear. Therefore, this study aims to analyze renal biopsy data from different regions in China to figure out the prevalence and trend of IgAN.

Methods: Through systematic electronic search of the PubMed, Embase, China National Knowledge Infrastructure (CNKI), Chinese Biomedical Literature Database (SinoMed), Cochrane Library and Wanfang databases from inception to March 1, 2023. The search keywords included: "renal biopsy", "renal pathological diagnosis" and the names of the different provinces, municipalities and autonomous regions. After completed the electronic database search, we performed a manual search of professional medical journals and thesis.

Results: After collecting and analyzing literatures, we sorted out renal biopsy data of 143176 patients with primary glomerulonephritis from 34 provinces of China, of which 39.73% were IgAN (in total of 56886 cases). The proportions of male and female patients were 58.67% and 41.33%, respectively. The proportion of IgAN patients was higher in economically developed provinces and municipalities. The weighted average prevalence before 2010 and after 2010 was 40.45% and 37.74%, respectively.

Conclusions: IgAN remains the most common biopsy-proven primary glomerulonephritis in China. The prevalence of IgAN was 39.73% in China and was higher in developed provinces and municipalities than in other areas. The weighted average prevalence of IgAN in China decreased slightly after 2010 than before 2010.

PUB286

Low Levels of Hemoglobin Are Associated with Critical Illness and Predict Disease Course in Patients with ANCA-Associated Renal Vasculitis

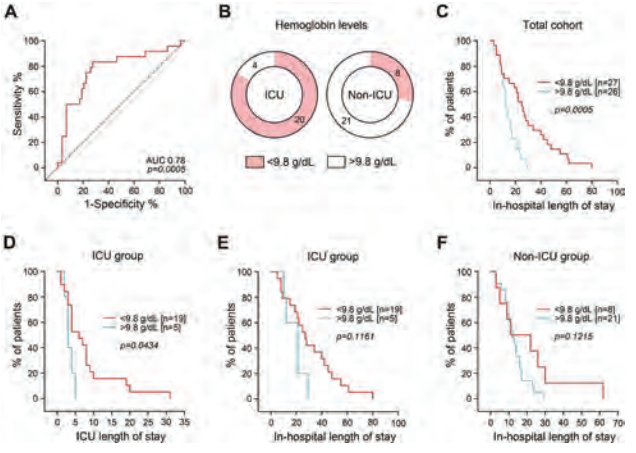
Eva Baier, Bjoern Tampe. *Universitatsmedizin Gottingen Klinik fur Nephrologie und Rheumatologie, Gottingen, Germany.*

Background: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is a small vessel vasculitis (SVV) often leading to critical illness by multi organ failure. Data for patients with specifically ANCA associated renal vasculitis requiring intensive care unit (ICU) supportive care are limited and have mainly focused on long term renal and overall outcome. Particularly, data on critical illness during the initial course of disease are scarce and remain poorly determined. Therefore, the purpose of this retrospective study was to identify predictors of critical illness in a cohort of patients with ANCA associated renal vasculitis.

Methods: We retrospectively included a total number of 53 cases with biopsy-proven ANCA associated renal vasculitis between 2015 till 2020 in a single center cohort study. Clinical data assessment enclosed age, sex, date of admission, discharge, and ward transfer during hospitalization, parameters relevant for ICU treatment, such as initial heart rate, mean arterial pressure, body temperature, urine output, serum creatinine, eGFR, sodium, potassium, white blood cells, platelets, pH, and hemoglobin levels at admission. A nonICU (*n=29*) and an ICU group (*n=24*) was formed. Between group comparisons, correlative analyses by means of multiple logistic regression and survival curve analyses were conducted.

Results: We here identified an association between low hemoglobin levels and requirement of ICU supportive care in patients with ANCA associated renal vasculitis. Levels of hemoglobin below 9.8 g/dL at admission independently predicted prolonged requirement of ICU supportive care in critically ill patients with ANCA associated renal vasculitis.

Conclusions: We here expand our current knowledge that low levels of hemoglobin negatively affect short term outcome in ANCA associated renal vasculitis, further improving our current understanding for the role of anemia in autoimmune kidney diseases.



PUB287

Unexpected Biopsy Finding in a Hispanic Man

Gabriel J. Torres-Rivera, Carlos S. Rosado-Rodriguez, Carlos Cortes, Jesenia M. De Jesus Alvarez, Cyndia Rodriguez Negron. *VA Caribbean Healthcare System, San Juan, Puerto Rico.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare primary glomerular disease with a very poor prognosis. Defined by the ultrastructural finding of haphazardly arranged, straight fibrils measuring 10 to 30 nm in thickness, deposited in the mesangium, glomerular basement membranes or both. On immunofluorescence, deposits typically stain for polyclonal IgG and complement. These changes are found in 0.5 to 1% of native kidney biopsies. FGN is more often seen in Caucasians compared to Hispanics, with a ratio of 100:1. We present a case of an Hispanic man with chronic proteinuria and progressive kidney disease with unforeseen biopsy findings.

Case Description: A 72 y/o Hispanic man was seen for the first time at nephrology clinics due to a progressive decrease in eGFR and nephrotic range proteinuria. Already a CKD IV, normal A1c and work up for causes of proteinuria (including C3, C4, UPEP, SPEP, HIV, Hep B/C) was non contributory. Age appropriate cancer screening was negative. ANA was positive at 1:320 with diffuse speckled pattern. Anti-PLA2R was also found normal. The patient eGFR and proteinuria remained stable, without nephrotic syndrome for 3 years. He presented to the ER due to elevated blood pressure and found with increase in creatinine to 3.5mg/dl from 2.7mg/dl. Proteinuria quantified at 5.2g/day and noted with glucosuria without hyperglycemia. ANA positive at 1:80 with speckled pattern, and DS-DNA negative. Biopsy showed changes suggestive of membranous glomerulopathy based on LM and IF as well as tubules with calcium oxalate casts. EM later reported fibrillary deposits consistent with fibrillary glomerulopathy. Kidney function improved and blood pressures were controlled, and he was discharged home for continued follow-up at clinics.

Discussion: FGN typically presents with proteinuria (usually nephrotic), hematuria, kidney insufficiency, and hypertension. It is typically associated to malignancies, autoimmune disorders, and dysproteinemias with only 7% being associated to membranous nephropathy. It is extremely rare in Hispanics. Renal prognosis is dire with average time to dialysis being 87 months. Although there is no available treatment, clinicians should be aware of this possibility of a diagnosis as planning and educating patient about the poor prognosis such diagnosis entails can lead to better outcomes with early preparedness.

PUB288

A Case of Dialysis-Dependent Rapidly Progressing C3 Glomerulonephritis

Samir Hirpara,[1,2] Morgan Hedden,[1,2] Alison Nguyen,[1,2] Renu Regunathan-Shenk,[3] Paul S. Modlinger.[3] *[1]Inova Fairfax Hospital, Falls Church, VA; [2]University of Virginia, Charlottesville, VA; [3]Virginia Nephrology Group, Fairfax, VA.*

Introduction: We present a case of dialysis-dependent rapidly progressing C3 glomerulonephritis (GN) without evidence of infection or paraproteinemia.

Case Description: Our patient (pt) is a 72-year-old male who presented with a subacute history of weight loss, fatigue, bilateral flank pain, and anasarca. Given his non-specific presentation, he initially went to an oncologist. Workup including bone marrow biopsy and serum protein electrophoresis was unremarkable aside from a creatinine elevation from a baseline of 0.8 (1 month prior) to 7.4 mg/dL. After admission to the hospital, he initiated hemodialysis for acute kidney injury. Autoimmune evaluation revealed negative anti-nuclear cytoplasmic antibody (ANCA), negative double-stranded DNA, low complement C3 (25 mg/dL), normal complement C4 (17 mg/dL), and anti-nuclear antibody testing (ANA) was weakly positive (1:160, speckled appearance). Repeat serum protein electrophoresis with immunofixation was negative. Infectious evaluation including urine culture, blood cultures, and a transthoracic echocardiogram was also negative. Renal biopsy revealed crescentic C3 GN. He was started on prednisone with plans to initiate cyclophosphamide pending insurance clearance. However, within 4 weeks, the pt recovered off of dialysis prior to the initiation of cyclophosphamide. The patient has continued on a steroid taper and was initiated on mycophenolate mofetil 1,500 mg twice daily. His most recent metabolic panel showed a creatinine of 0.78 mg/dL and persistent microscopic hematuria at approximately 5 months since diagnosis.

Discussion: To our knowledge, this is the first reported case of dialysis-dependent C3 GN which improved with steroid treatment alone. It remains unclear if the patient experienced post-infectious GN from an unidentified infection versus an idiopathic C3 GN with rapid progression.

PUB289

Porphyria Cutanea Tarda and Systemic Lupus Erythematosus: An Unusual Association in a Patient with Nephritic Syndrome

Caroline F. Carrera, Ricardo M. Borges, Washington A. Freire Filho, Felipe Carvalho Barros Sousa, Liliana M. Kassar, Livia B. Cavalcante, Lectícia Jorge, Cristiane B. Dias, Luis Yu. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Introduction: Porphyria Cutanea Tarda (PCT) is a metabolic disorder caused by reduced activity of enzyme uroporphyrinogen decarboxylase in the liver, generating accumulation of porphyrinogens. It is a rare photodermatosis that manifests as hemorrhagic blisters, hyperpigmentation and hypertrichosis. The most commonly found susceptibility factors are infection by C virus and HIV, alcohol abuse, smoking and exposure to estrogens. Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by production of autoantibodies and systemic inflammation, in which lupus nephritis occurs in about 60% of cases.

Case Description: White male patient, 59 years, whose history of tense bullous lesions started in 2020 on the upper and lower limbs and thorax. Skin biopsy showed subepidermal cleavage, papillary dermis with scalloped appearance and vessel wall thickening suggestive of PCT, in addition to Elevated urinary porphyrins. In the last year, this patient started nephritic syndrome with hypertension, hematuria, mild proteinuria and creatinine elevation from 1.2 mg/dl to 2.0 mg/dl associated with positive ANA and complement consumption. The renal biopsy showed membranoproliferative and membranous pattern, an aspect suggestive of Class III+V Lupus Nephritis and signs of chronicity. Immunosuppressive treatment, photoprotective therapy and hydroxychloroquine were initiated.

Discussion: There are few reports in the literature of the simultaneity between PCT and SLE becoming a therapeutic challenge. Some studies suggest that chronic pro-inflammatory state generated by PCT could trigger an autoimmune response such as SLE in patients with mutual genetic susceptibility. Our patient showed good control of skin lesions using hydroxychloroquine. Considering signs of chronicity and little activity in renal biopsy, maintenance treatment for lupus nephritis was initiated with Mycophenolate and low doses of corticosteroids.

PUB290

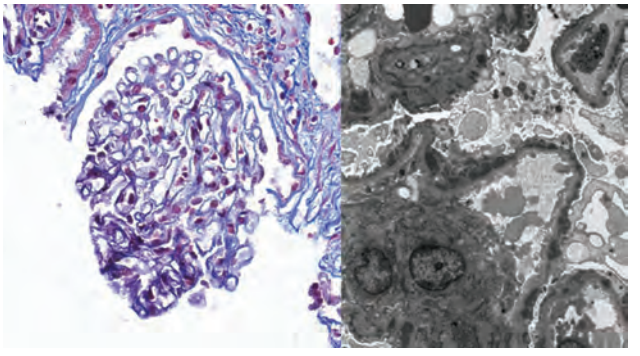
A Case of Syphilis-Induced Secondary Membranous Nephropathy

Hima B. Doppalapudi,[1,2] Luis B. Caraballo,[1,2] Vijay K. Vanguri,[1,2] Kirti Basil.[1,2] *[1]UMass Memorial Medical Center, Worcester, MA; [2]University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Secondary membranous nephropathy (SMN) is typically caused by drugs, infections, autoimmune disorders, or malignancy. Although the association between syphilis and renal disease was first identified over 100 years ago, renal involvement has been infrequent especially in the US, but has been rising. This case elucidates SMN due to syphilis with dramatic resolution of proteinuria with antibiotics.

Case Description: A 41-year-old woman with history of intravenous drug use presented with acute onset of gross anasarca and frothy urine. She was found to have serum creatinine of 1.6 mg/dL, serum albumin of 2.0 mg/dL, and nephrotic range proteinuria of 25 g/g. Urine sediment was bland without casts or cells. A renal biopsy revealed an immune-complex mediated glomerulopathy with a membranous pattern of injury and "full house" immunoreactivity. Rheumatological workup for lupus was negative, with negative ANA, dsDNA, normal C3, and low C4. Anti-PLA2R was also negative. Of note, she had recently tested positive for chlamydia, gonorrhea, syphilis, and received appropriate antibiotic therapy. She did not follow up in clinic until 6 weeks later to discuss immunosuppression, which was not given as she was noted to have complete resolution of proteinuria, and her creatinine and serum albumin returned to baseline.

Discussion: Etiologies of SMN are diverse and differentials are broad, especially when clinical, morphological and immunostaining do not fit classic presentations. Possible renal manifestations of syphilis include membranous, glomerular, and non-glomerular conditions, with membranous nephropathy being the most common. Although the exact pathophysiology is unknown, renal biopsies have shown presence of immune complexes containing anti-treponemal antibodies. Immunofluorescence stains for IgG, C3, IgA, IgM and C1q, also known as "full-house" pattern. As in our patient, renal response to appropriate treatment of syphilis was dramatic, and possibility of syphilis should be considered in new diagnoses of MN with full-house immunoreactivity to avoid unnecessary immunosuppression.



PUB291

Successful Treatment of Co-Existing IgA Nephropathy and Collapsing FSGS with SGLT2i and Steroids

Sakil A. Bhuiyan, Hira Tahir, Chelsea C. Estrada. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: IgA nephropathy (IgAN) is the most common lesion to cause primary glomerulonephritis and occurs most commonly in Asian individuals. While focal segmental glomerulosclerosis (FSGS) has been reported to co-exist with IgAN, the co-existence of the collapsing subtype of FSGS (cFSGS) with IgAN is rarer and has notoriously few treatment options and poor renal prognosis. Here we report a case of IgAN and cFSGS with near 60% improvement in proteinuria after co-administration of prednisone and the sodium-glucose cotransportor-2 inhibitor (SGLT2i), dapagliflozin.

Case Description: A 50 year-old Asian male with history of CKD stage 3 (baseline creatinine 1.7 mg/dL), anti-phospholipid syndrome, and hypertension was noted on routine follow up to have increasing proteinuria, quantified at 5.9 g/day, which was up from 2.7 g/day two years previously (patient lost to follow up during COVID-19). Patient denied history of recent COVID infection or smoking. On examination he was normotensive on home BP meds of losartan 100 mg and metoprolol 50 mg daily. His BMI was 27 and he had no edema. Labs revealed an albumin of 3.5 g/dL, Cr 1.7 mg/dL and UA was negative for hematuria. Serologies including HIV, Hepatitis panel, ANA and PLA2R Ab were negative. Renal biopsy revealed IgAN and cFSGS with 25% tubular atrophy and interstitial fibrosis. His proteinuria continued to rise after renal biopsy to a peak of 6.3 g/day and decision was made to initiate Prednisone 80 mg daily and Dapagliflozin 5 mg daily. Prednisone was tapered after two months and by month three proteinuria improved to 2.7g/day, close to 60% reduction, while creatinine remained stable.

Discussion: Here we describe an interesting case of IgAN and cFSGS with successful partial remission achieved with the combination therapy of Prednisone and Dapagliflozin, on the background of Losartan. Generally, the co-existence of IgAN and cFSGS portends dismal prognosis with one report citing 90% ESRD rate. While dapagliflozin has been approved for treatment of IgAN, its use in cFSGS has not been clearly established. Further studies like this are necessary to determine management for either isolated or co-existing IgAN and cFSGS.

PUB292

Elevated Inflammatory Biomarkers Are Risk Factors for Composite Outcome in South Asian IgA Nephropathy (IgAN)

Suceena Alexander,[1] Santosh Varughese,[1] Jonathan Barratt,[2] George John.[1]
GRACE-IgANI. *[1]Christian Medical College Vellore, Vellore, India; [2]University of Leicester, Leicester, United Kingdom.*

Background: The role of placebo controlled immunosuppression (IS) trial in high-risk South Asian IgAN is still controversial. The effect of IS on longitudinal biomarkers can be surrogate end-points for assessing its impact on CO.

Methods: Serum APRIL levels were measured in baseline and longitudinal sera (1year, 2year) by ELISA. Serum Gd-IgA1 levels were measured in baseline and longitudinal sera (1year, 2year) using KM55 ELISA. Serum levels of TNF-RI, CD27 & BCMA were quantified with a Luminex multiplex assay. CO was defined as ≥50% fall in eGFR (CKD EPI) from baseline and/or eGFR (CKD EPI) <15ml/min/1.73m² or RRT/death. Partial remission (PR) in proteinuria was defined as decrease of 24-hour urine protein by 50% from baseline and <3g/day if nephrotic at baseline OR proteinuria <1.5g/day if non-nephrotic at baseline for at-least three months.

Results: Out of 201 IgAN patients, 37% of patients reached composite outcome (CO) in 3 years in the GRACE-IgANI cohort. Treatment group II (high-risk group with IS) had 146 patients. The mean time to PR in proteinuria was significantly longer in the CO group (10 vs. 6months, p= 0.005). Achieving less than <1g/day at 6month significantly increased renal survival (36 vs. 22months, p<0.001). There was significant longitudinal increase in serum APRIL levels from baseline to 2year in patients with favourable renal outcome. The longitudinal decrease in serum Gd-IgA1 levels at 6month paralleled the serum IgA levels. There was significant association between baseline inflammatory markers (TNF-R1, CD27 & BCMA) and CO at 3 years whereas baseline elevated hsCRP levels showed a global decrease over time.

Conclusions: Placebo-controlled trial in this high-risk population entails ethical considerations hence assessing the known impact of IS on surrogate end-points can potentially guide rational therapy.

Outcomes of Inflammatory Bowel Disease-Related IgA Nephropathy

Salman B. Mahmood,[1] Manesh Kumar Gangwani,[4] Nathaniel Klair,[1] Wade M. Lee-Smith,[3] Prasanth Ravipati,[2] Scott Reule,[1] Patrick H. Nachman.[1]
[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]University of Nebraska Medical Center, Omaha, NE; [3]The University of Toledo Libraries, Toledo, OH; [4]The University of Toledo Medical Center, Toledo, OH.

Background: Case reports have linked IgA nephropathy (IgAN) and inflammatory bowel disease (IBD) but data remains sparse. We describe a patient cohort with IBD associated IgAN from the nationwide VA database.

Methods: We retrospectively studied patients with IBD who had kidney biopsy confirmed IgAN. We also conducted a systematic search of electronic databases through 2022 using the terms "IBD" and "IgAN" to synthesize the existing literature on this topic.

Results: 25 subjects were included: all men with age 64.2 ± 13 years (mean ± SD), eGFR 41 ± 28 mL/min and UPCR 3.1 ± 3.2 g/g. 74% received RAAS blockade and 55% required immunosuppression. 28% developed ESKD and 48% died during a follow-up period of 56 ± 49 months (Table 1). The literature search yielded only 3 series of patients with IBD-IgAN (Table 2), prohibiting any pooled analysis.

Conclusions: Our study adds to the limited data regarding IBD-IgAN and highlights the poor outcomes associated with this disease. Large, prospective, multicenter studies are needed to better characterize this association.

Bridging the Gap in Understanding Variations Between Indo-Asian and White Ethnicities in ANCA Vasculitis

Lauren Floyd,[1] Joshua Storrar,[2] Sanjeev Pramanik,[1] Adam Morris,[1] Smeeta Sinha,[2] Philip A. Kalra,[2] Ajay P. Dhaygude.[1] *[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom.*

Background: ANCA associated vasculitis (AAV) is a rare autoimmune condition predominantly seen in white Caucasian populations. There are variations in AAV worldwide and little is known about outcomes in ethnic minority patients in particular Indo-Asian populations.

Methods: A multicentre, retrospective cohort study of patients with AAV and who self-identified as belonging to the following ethic groups; 'Indian, British Indian, Pakistani, British Pakistani, Asian or Asian British' was carried out. The study included patients from 2 regional centres in the North West, UK, between 2009 and 2023. A 2:1

ratio of consecutive white patients was included as a control cohort for comparison with Indo-Asian patients. Data collection included demographics, renal histology and clinical outcomes.

Results: The demographics of each cohort are presented in Fig.1. GPA was observed in 54% and MPA in 46%. There were significantly more diabetics (P=0.002) and history of TB (P=0.019) in the Indo-Asian group. There was similar distribution of organ involvement and baseline laboratory results including eGFR. Berden's classification was similar although there were higher rates of crescentic class in the Indo-Asian group (36% v 13%) and a greater number in the medium and high-risk groups of the RRS (71% v 52%). Similar rates of RRT at presentation, relapse, ESKD and mortality were observed.

Conclusions: Our findings suggest Indo-Asian patients tend to be younger and have a higher prevalence of diabetes, previous TB exposure and abnormal glomeruli on biopsy. Further research is required to comprehend the genetic contribution to AAV's pathogenesis and clinical phenotype, as well as establishing if disparities among ethnic minorities arise from genetic and / or environmental factors, so as to enhance patient outcomes.

A Case of Relapsing Pauci-Immune Glomerulonephritis After Soft Tissue Infections

Gisele Vajgel, Italo R. Alves, Lucas S. Xavier, Thais O. Santos, Lucila Maria Valente, Camila B. Oliveira, Denise M. Costa. *Hospital das Clinicas, Recife, Brazil.*

Introduction: The association between infections and vasculitis relapses is well established, especially after airway infections and endocarditis. However, pauci-immune glomerulonephritis (PIGN) after infection is still poorly described, particularly after cutaneous infection, and the most appropriate management in this context is still unclear. We report a case of a recurrent PIGN after two episodes of soft tissue infections.

Case Description: A 51-year-old man was seen with erysipelas in left lower limb. He had a medical history of obesity and two episodes of thrombosis in the left femoral vein, with negative tests for thrombophilia. On the 7th day of treatment with amoxicillin/clavulanate, he had red urine and decreased urine output, with serum creatinine (sCr) 4.5 mg/dl; urinalysis with acanthocytes and traces of protein. He lost follow-up and was seen by a nephrologist 4 months later with sCr 1.2mg/dL (same as baseline), microscopic hematuria and urine albumin-creatinine ratio (uACR) 198 mg/g. A few days later, he was admitted with bullous lymphangitis and received piperacillin-tazobactam plus teicoplanin. Despite clinical improvement of infection and absence of other symptoms, he developed rapidly progressive glomerulonephritis (sCr 10.7, dysmorphic hematuria, red cell casts and uACR 1117 mg/g) and needed hemodialysis. Viral serologies were negative and complement levels were normal. Renal biopsy revealed 1/12 glomeruli globally sclerotic, 2 fibrous crescents and foci of rupture of the glomerular basement membrane with interstitial fibrosis and tubular atrophy of 35-45%, without deposits at immunofluorescence and electron microscopy, characterizing a PIGN with crescents in sclerosing phase. The patient recovered renal function until discharge with Cr 1.3 without immunosuppressive treatment. After 10 months, he remains in clinical and laboratory remission.

Discussion: There is evidence of association of bacterial infections with vasculitis relapses, however soft tissue infections are infrequently reported. Furthermore, recurrence of PIGN associated with infections in the same patient is also quite uncommon. The present case showed that PIGN associated with infection can have a favorable outcome after treating the infection without immunosupression.

PUB296

Cohort of Mexican Patients Diagnosed with IgA: Mortality and Requirement for Renal Support Therapy

Roxana Villanueva Macedo, Juan O. Romero Tafoya, Javier Soto-Vargas, Carlos A. Villavicencio López, Renato Parra Michel, Hugo B. Espinoza, José J. Gutiérrez Hernandez, Jesus A. Vega Lopez de Nava, Paulina De Niz Hernández, Rubén Lara Monterrubio, Mauro Montemayor. *Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: IgA glomerulonephritis is the most frequent type among primary glomerulonephritis (GN), with highly uneven incidence due to population differences, biopsy indications, and variable outcomes. Mortality and the need for kidney replacement therapy (KRT) were determined in a cohort of renal biopsies conducted on Mexican population.

Methods: Retrospective cohort study on patients with a histological diagnosis of primary IgA nephropathy, from June 2017 to May 2022. The primary objective was mortality and the requirement for renal support therapy.

Results: 692 patients were followed up for 5 years, of which IgA glomerulonephritis accounted for 18% (33 cases), with 33% being female and 66% male. The average age of presentation was 17±1, and the average glomerular filtration rate (GFR) was 77 ml/min/m. 30% progressed to chronic kidney disease, none required renal support therapy, and there was a mortality rate of 6% (2 cases). Conclusions: IgA nephropathy remains one of the primary and most relevant glomerulonephritis in young patients, with a progression to end-stage renal disease within a short period. Therefore, timely diagnosis is of utmost importance for identification and treatment.

Conclusions: IgA nephropathy remains one of the primary and most relevant glomerulonephritis in young patients, with a progression to end-stage renal disease within a short period. Therefore, timely diagnosis is of utmost importance for identification and treatment.

Exostosin 1- and 2-Associated Lupus-Like Membranous Nephropathy in Men

Kana R. Amari, Shikha Wadhwani, Yonatan A. Peleg. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: The detection of Exostosin (EXT) 1 and 2 through immunofluorescence (IF) has predominantly been linked to secondary forms of membranous nephropathy, often observed in autoimmune disorders. This report presents two cases of Caucasian males with no known autoimmune conditions who exhibited de novo lupus-like membranous nephropathy with Exostosin positivity.

Case Description: A 61-year-old man presented with subacute onset nephrotic syndrome a few weeks after a COVID-19 infection. His laboratory showed a creatinine (Cr) of 2.3 mg/dL (baseline 1.4 mg/dL), peak proteinuria 34 g/g by 24h uPCR, microscopic hematuria, albumin 2.3 g/dL. Serologic workup with strongly positive RF, low C4, ANA >1:1280, negative reflex, cryoglobulin, hepatitis B and C, and phospholipase A2 receptor antibodies (aPLA2R). His kidney biopsy showed subepithelial immune deposits, no tubuloreticular inclusions (TRI), and no cryoglobulinemic deposits on electron microscopy (EM), and full-house pattern by IF with EXT 1 positivity. He was treated with mycophenolate, tacrolimus, and steroid taper. One year later, he achieved remission: cr 1.6 mg/dL, albumin 4 g/dL, 24h uPCR 0.4 g/gCr. A 57-year-old man with a history of mantle cell NHL in remission and chronic VTE, presented for evaluation of nephrotic syndrome. He had a stable Cr of 1.1 mg/dL, proteinuria 12.5 g/24h, microscopic hematuria, albumin 2.4 g/dL. Serologic workup with ANA >1: 1280, dsDNA 1:40, +RNP, +SM Ab; and unremarkable aPLA2R, C3/C4, hepatitis B and C, syphilis, HIV, and parvovirus. Kidney biopsy showed subepithelial and subendothelial deposits and TRI on EM, with full-house pattern and EXT 2 positivity on IF. The patient was treated with tacrolimus and mycophenolate. At 2 months, his Cr is stable, proteinuria is persistent, but albumin improved to 3 mg/dL.

Discussion: Exostosin-associated membranous nephropathy (EMN) is a favorable kidney prognosis subgroup primarily found in young women with autoimmune conditions. Our report observed two males with lupus-like membranous nephropathy (MN) but no systemic lupus symptoms who met the SLICC criteria for standalone renal involvement. Triggers for EMN are unclear in an atypical age and gender presentation, but a high interferon state from prior chemotherapy or a recent COVID-19 infection may play a role. Further research is needed to understand mechanisms. Initial multitarget therapy shows promise in treatment.

PUB298

Unmasking Lupus: The Great Masquerader

Roopali Dahiya. *ABVIMS and Dr RML Hospital, Delhi, India.*

Introduction: Pyrexia of unknown origin (PUO) has always been a challenging condition that an internist comes across. Infections, inflammatory diseases and neoplasia are among the common etiologies of it. Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that can virtually affect any organ and is a significant cause of morbidity and mortality. Here we present a case of SLE as the cause of PUO due to its rare occurrence in a young male and presentation as an infective endocarditis mimic.

Case Description: An 18 year old Asian male presented with fever and hematuria for 2 months. Examination revealed bilateral infrascapular pleural rub, a pansystolic

murmur in left parasternal area and tender hepato-splenomegaly. Initial lab reports showed anemia (Hb 6.9 gm/dl), neutrophilic leukocytosis with schistiocytes, urea 127 mg/dl, creatinine 3.1 mg/dl, deranged liver enzymes, hypoalbuminemia with hematuria 3+ and proteinuria 4+. HRCT chest showed multiple cavitatory nodules in bilateral peripheral lung fields with mild pleural and pericardial effusion. Blood and urine cultures were sterile, but inflammatory markers were persistently raised. Echocardiography was performed, which revealed vegetations along the tricuspid valve. Transesophageal echocardiography confirmed 1x1cm vegetation above the leaflet of tricuspid valve. A working diagnosis of infective endocarditis was kept, and treatment with ceftriaxone and vancomycin was started. As the patient was not improving, the possibility of autoimmune aetiology (although rare in males), was kept among differentials. An autoimmune workup showed ANA and anti-ds DNA antibodies positivity, low C3 and C4 and negative ANCA and APLA profiles. A renal biopsy confirmed class 3 focal lupus nephritis with acute tubular necrosis. Based on 2019 ACR/EULAR SLICC criteria, a diagnosis of SLE with class 3 lupus nephritis with isolated culture-negative tricuspid valve Libman- Sacks endocarditis was made. There was drastic improvement in patient's symptoms and kidney and liver functions post-methylprednisone and cyclophosphamide pulse.

Discussion: Our case is special since it highlights the diagnostic dilemma between infective endocarditis and SLE in a young male. Both diseases have totally different treatment algorithms and prognosis. Hence, SLE should be considered in the differentials of PUO for timely therapeutic intervention to control the progression of the disease.

PUB299

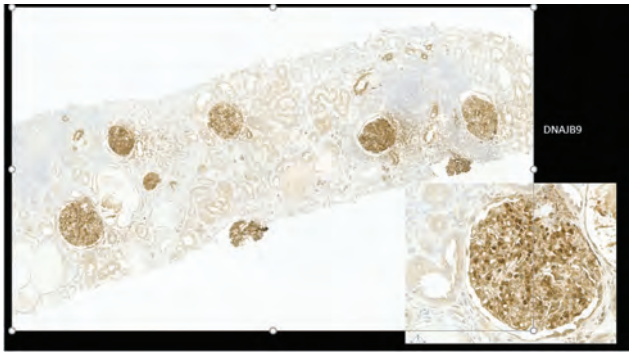
A Brief Clinical Course of Fibrillary Glomerulonephritis

Roy Rajan,[1,2] Alex D. Tarabochia,[1,2] Tracy L. Ingersoll,[2] Thomas M. Kaneko,[1,2] Jason R. Pettus,[1,2] Charles W. Hopley,[1,2] Clay A. Block.[1,2] *[1]Dartmouth College Geisel School of Medicine, Hanover, NH; [2]Dartmouth Health, Lebanon, NH.*

Introduction: Fibrillary Glomerulonephritis (FGN) can be primary or secondary as in cases, associated with malignancies. The presence of DNAJB9, a heat shock protein, in the glomeruli is > 98% sensitive and specific for FGN.

Case Description: 62-year-old man with history of long standing hypertension, CKD 3A, with baseline creatinie of 1.6 mg/dL, presented to emergency room with shortness of breath and edema in October 2020. He was on ibuprofen 600 mg three times daily for pain 3 months prior to that, and his creatinine was found to be 4.6 mg/dL. He had normal sodium, potassium, calcium and bicarbonate with low serum albumin of 2.2 mg/dL (3.5- 5). He was diuresed and his creatinine trended down to 2.6 mg/dL. He saw a nephrologist 6 months later and was found to have 15 grams of proteinuria on spot urine collection, with albumin of 3.2 (3.2- 5.2), but was lost to follow up. During that time, he was diagnosed with prostatic adenocarcinoma with extension to seminal vesicles, and involvement of iliac and obturator lymph nodes. He was started on anti androgen therapy with gonadotropin-releasing hormone (GnRH) antagonist degarelix, and GnRH analogue Leuprore, and also treated with brachytherapy. In July 2022 and was found to have a creatinine of 3.15 mg/dL, but with dereased protinuria of 4.5 on spot collection. Renal biopsy done showed Fibrillary GN, DNAJB9 positve with background moderate chronic interstitial nephritis with interstitial fibrosis and tubular atropy of about 30%. He was started on Lisinopril for his proteinuria, since the fibrillary GN was presumed secondary to his protate adenocarcinoma, and his creatiniene since then has remained stable at 3.33, and proteinuria of 4.5.

Discussion: This case illustrates the importance of renal biopsy in evaluating renal insufficiency, especially when there are confounding factors that can cause acute kidney injury. There is no specific treatment of FGN, but treating the underlying cancer seems to keep patient's renal function stable.



PUB300

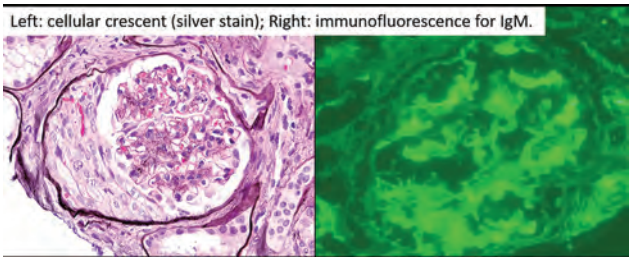
Antineutrophil Cytoplasmic Antibody-Associated (ANCA) Vasculitis Associated with Hydralazine

Sarah Jawadi, Jorge L. Endara, Chaitanya A. Pal, Raja Ravender, Sara Combs, J. Pedro Teixeira, Pablo Garcia. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Hydralazine is a commonly used antihypertensive agent, but its use has been associated with drug-induced autoimmune diseases such as lupus and ANCA vasculitis. We present a case of severe hydralazine-induced ANCA vasculitis.

Case Description: A 68-year-old man with hypertension treated with hydralazine for 18 months and chronic kidney disease (CKD) with baseline creatinine (Cr) 1.5 mg/dL is admitted with acute kidney injury. Exam was notable for lower extremity edema. Labs included Cr 13.4 mg/dL, urinalysis with >150 RBCs/HPF, and spot urine/protein creatinine ratio 1.54 g/g. This prompted serologic testing, including antinuclear antibody (ANA) titer 1:640, ANCA titer >2560, anti-proteinase 3 (PR3) 3.4 AI, and anti-myeloperoxidase (MPO) antibody >8.0 AI. C3 was low at 65 mg/dL with normal C4. We initiated hemodialysis (HD), pulse corticosteroids, and 5 sessions of plasmapheresis. Renal biopsy revealed focally crescentic glomerulonephritis (GN) with 2+ IgM and C3 staining. His course was complicated by post-biopsy perinephric hematoma requiring embolization and bowel perforation requiring laparotomy. Ultimately further immunosuppression was held. He remains on HD 6 months later.

Discussion: Hydralazine-induced ANCA vasculitis is uniquely characterized by frequent dual MPO and PR3 positivity, positive ANA, hypocomplementemia, and low-level glomerular immune complex deposition. Immunosuppression is usually required despite discontinuation of hydralazine, with outcomes similar to other forms of ANCA GN. Indeed, in the absence of immunosuppression which was preclude by other complications in this case, renal prognosis is poor.



PUB301

Pauci-Immune ANCA(-) Extracapillary Glomerulonephritis in a Patient with Systemic Lupus Erythematosus (SLE)

Enrique F. Morales Lopez, Juan D. Diaz Garcia, Francisco J. Hernandez Copca, Ydris Z. Rosillo-Salgado, Victor M. Ulloa Galvan, Jose L. Ortega, Martin B. Yama Estrella, Mario Alamilla-Sanchez. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Introduction: Although ANCA was first associated with primary vasculitides, it is now clear that 15-20% of lupus patients have ANCA+, in some cases, although negative, histological features are the cause for suspicion. in this entity.

Case Description: A 29-year-old female with SLE diagnosed in 2019 presented hematological and mucocutaneous disease, ANAs laboratories 1:160, with induction treatment for one year based on azathioprine, prednisone and hydroxychloroquine. In 2021 she presents with proteinuria of 672 mg and hematuria, creatinine of 0.9 mg/dl, treatment with mycophenolic acid. One year later, she had an increase in proteinuria of 703 mg/dl, ANCAs PR3 and MPO negative. She integrates hematuria proteinuria syndrome, without deterioration of renal function, eucomplementemic. Kidney biopsy active extracapillary hypercellularity, cellular crescents with active extracapillary lesion with fibrocellular crescents. Prominent and vacuolated podocytes, interstitium with patches of fibrosis with tubular atrophy, IFI with positive IGG, positive C3C, active and chronic extracapillary proliferative glomerulonephritis with scant deposits of immune complexes. By histopathology, ANCA (-) vasculitis is suspected. Therefore, treatment with cyclophosphamide was started, with subsequent improvement in proteinuria.

Discussion: Crescentic glomerulonephritis is a severe form of glomerular lesion characterized by Bowman's capsule proliferation and fibrinoid necrosis, which implies little or no Ig deposition at the glomerular level, which is why it is called pauciimmune. This type of lesions associated with SLE are very rare and even more so in the context of negative ANCA, we present the case to take this type of histological presentation into account.

PUB302

Signs and Symptoms at Diagnosis in Patients with C3 Glomerulopathy: Results from a Real-World Multi-Country Study

Richard A. Lafayette,[1] Katharina Pannagl,[2] Briana C. Ndife,[3] Serge Smeets,[4] Kathleen Murphy,[3] Jonathan de Courcy,[5] Susanna Libby,[5] Clare Proudfoot.[4] *[1]Stanford University School of Medicine, Stanford, CA; [2]Novartis Pharmaceuticals UK Ltd, London, United Kingdom; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [4]Novartis Pharma AG, Basel, Switzerland; [5]Adelphi Real World, Bollington, United Kingdom.*

Background: Complement 3 glomerulopathy (C3G) is a rare kidney disease, with an estimated incidence of 1-2/million/year. C3G associates with a high risk of disease progression, up to 50% of patients reach kidney failure within 10 years of diagnosis (Dx). Signs and symptoms include proteinuria, hematuria, edema, hypertension and fatigue. This analysis aimed to understand the signs and symptoms of C3G from patients in the US, Europe and Asia, at the time of Dx.

Methods: Data were drawn from the Adelphi C3G Disease Specific Programme, a cross-sectional survey with retrospective data, of C3G-treating nephrologists in US,

France, Germany, Italy, Spain, UK (EU5), China and Japan between August 2022 and April 2023. Nephrologists completed forms for consecutive patients presenting with C3G. The forms included demographic and clinical information including signs, symptoms and lab values.

Results: 111 nephrologists completed records for 385 C3G patients (US 100, EU5 189, China 60, Japan 36). Median patient age at Dx was 38.8 years, and 59% were men. Median eGFR at Dx was 49.0 ml/min/1.73m^2. Median proteinuria at Dx was 3.4 g/day and was ≥1 g/day in 85% of patients. The other most common signs and symptoms were hematuria, edema, hypertension and fatigue. Discolored urine, pain and appetite loss were also reported (**Table 1**). Physicians perceived disease severity at Dx as moderate in 50% and as severe in 34% of patients.

Conclusions: C3G patients experience symptomatic and clinical burden at Dx. This symptom burden, high proteinuria, and relatively low eGFR are consistent with physician assessment of moderate or severe disease at Dx. Effective Dx and treatment is an important goal to improve patient symptoms and disease.

Morphology-Based Assay for Podocyte Damage In Vitro

Pavlos Pissios, Nikolay O. Bukanov, Maria Chiara Magnone. *Janssen Research and Development LLC, Boston, MA.*

Background: Podocyte foot processes are crucial components of the glomerular filtration barrier. Foot processes are effaced in genetic or acquired forms of podocytopathies resulting in increased albuminuria and eventual kidney failure. Molecular changes underlying foot process effacement include remodeling of actin cytoskeleton leading to the detachment of podocytes from the glomerular basement membrane. In this study, we developed an assay to quantify changes in podocyte shape induced by a known podocyte-damaging agent, puromycin aminonucleoside (PAN), and prevention of the changes in shape using integrin beta 1 agonistic antibody that enhances podocyte adhesion to laminin.

Methods: Immortalized (Tert) human podocytes isolated from human urine were obtained from Evercyte. Podocytes were cultured on laminin-coated plates and exposed to increasing doses of PAN in combination with integrin beta 1 agonistic antibody. Changes in podocyte area and eccentricity (a metric of elongation) were analyzed in Incucyte. Changes in actin cytoskeleton were assessed by phalloidin staining.

Results: Exposure of podocytes to PAN caused a dose-dependent increase in cell area and rounding of podocytes. Application of integrin beta 1 agonistic antibody prevented the effects of PAN on podocyte shape likely acting on alpha 3-beta 1 integrin, the main podocyte integrin mediating its adhesion to laminin.

Conclusions: We developed a functional assay to model changes in podocyte shape *in vitro* using a known podocyte toxin, puromycin aminonucleoside. The assay could find applicability to other podocyte toxins and for screening for podocyte protective agents.

PUB304

A Unique Presentation of Lupus Podocytopathy with Collapsing FSGS Variant

Klodia Hermez, Amulya Rajagopal, Sandeep S. Soman, Kausik Umanath. *Henry Ford Hospital, Detroit, MI.*

Introduction: Lupus podocytopathy is a rare subset of lupus nephritis seen with nephrotic range proteinuria that presents with findings on kidney biopsy mimicking that of minimal change disease or focal segmental glomerular sclerosis (FSGS). A rare subset of collapsing glomerulopathy can also be seen. This condition has also been linked to the pathologic APOL-1 gene variant. We report a rare case of lupus podocytopathy with collapsing FSGS.

Case Description: A 42-year-old African American male with a history of hypertension and systemic lupus erythematosus (on mycophenolate mofetil (MMF) 1.5 g twice daily for non-renal manifestations) presented after outpatient labs showed dramatically increased serum creatinine and BUN. His only reported symptoms were shortness of breath and fatigue. In the ED, blood pressure was 148/84 mmHg. Labs showed serum creatinine of 10.23 mg/dL (baseline of 2.0 mg/dL), BUN of 111, bicarbonate of 9 mmol/L, and hemoglobin of 7.4 g/dL. The urine albumin to creatinine ratio was 1,463.5 mg/g with a urine protein to creatinine ratio of 2.91 g/g. COVID-19, flu A/B, hepatitis panel, EBV, CMV, HIV, blood cultures, and parvovirus were all negative. Kidney biopsy demonstrated acute tubular injury, WHO class II lupus nephritis, and collapsing FSGS in the setting of lupus podocytopathy. APOL-1 gene testing is pending. He was initiated on pulse dose steroids for 3 days, and hemodialysis was initiated due to worsening acidosis. He was continued on his home dose of MMF. He currently remains hemodialysis dependent (declared ESRD).

Discussion: Patients with SLE podocytopathy represent less than one percent of all SLE flares, with collapsing FSGS variant even more rare and associated with poor prognosis. In recent years the literature started defining non-HIV-related collapsing glomerulopathy, but no unified data regarding treatment guidelines exist. This patient was treated with a combination of steroids and MMF without success, highlighting a unique presentation of a rarely seen syndrome in lupus nephritis.

PUB305

Delaying Progression of Kidney Diseases in Patient with FSGS with Dietary Interventions

Haley D. Justus,[1] Muhammad Sohaib.[2] Strive Health. *[1]Strive Health, Hendersonville, NC; [2]Strive Health, Princeton Junction, NJ.*

Introduction: Plant-based diets along with lowering dietary protein intake can lower production of uremic toxins and may provide protection in advancing chronic kidney disease. Nutrition education should be provided via Registered Dietitian to optimize potassium and phosphorus intake in patients following plant-based diets in later stages of chronic kidney disease.

Case Description: 50-year-old male with histoy of chronic kidney disease stage V, hypertension, and cardiomyopathy. The etiology of his chronic kidney disease (CKD) is biopsy proven FSGS with IgA glomerulopathy. The patient was diagnosed with CKD in 2019 and had an AV fistula placed in 2022 in preparation for a dialysis start and is actively listed for kidney transplantation. On initial RD visit, patient voiced he follows a whole food and plant-based approach and reads food labels to limit inorganic phosphorus. Interventions to reduce serum phosphorus and potassium included: Continuance of lower protein diet by limiting animal-based protein portions to 3 oz., starting tums as a phosphate binder per nephrologist and double boiling potatoes and sweet potatoes. The patient had maintained GFR < 10 without start on dialysis as of April 2023. He reported no uremic symptoms and continued with good appetite. His proteinuria also improved from nephrotic range to non-nephrotic range with dietary interventions.

Discussion: High consumption of protein intake is associated with increased incidence and progression of kidney disease. Plant based diets have shown to slow down the progression of kidney disease by lowering intraglomerular pressure in patients with diabetes and hypertension however literature is lacking to support their use to delay progression in patients with glomerulopathies associated with proteinuria. Our patient has biopsy proven FSGS with Ig A nephropathy with rapid decline in kidney function which was stabilized after adopting plant-based diet and limiting protein intake. Additionally, proteinuria improved from nephrotic range to non-nephrotic range without the use of any antiproteinuric medication. Typically, normal recommendation for protein intake is 0.8-1.0g/kg body weight. CKD recommendations are 0.55-0.6 g/kg body weight non-diabetic and 0.6-0.8/kg body weight for diabetic patients. Side effects include elevated potassium and phosphorous levels, and early dietitian intervention can help mitigate these complications.

PUB306

Intradialytic Amino Acids Improved Malnutrition Markers in ESRD with Complex Congenital Heart Disease on Peritoneal Dialysis

Desiree de Waal, Macaulay A. Onuigbo. *University of Vermont Larner College of Medicine, Burlington, VT.*

Introduction: Peritoneal dialysis (PD) is a cost-effective, home-based therapy for ESRD. The use of amino acid-based solutions resulted in better preservation of the ultra-structure of the peritoneal membrane when compared to glucose containing products. Malnutrition in the PD patient leads to poor outcomes. Intraperitoneal Nutrition (IPN), a nutrition intervention strategy designed specifically for the malnourished PD patient, is non-invasive, well tolerated, yet underutilized. A major obstacle is insurance

non-coverage. IPN with amino acid-based PD solutions induce anabolic response in malnourished PD patients and serve as source of proteins and calories.

Case Description: A 51-year-old male patient with complex congenital heart disease including Tetralogy of Fallot with Eisenmenger physiology, on starting PD for ESRD, had significant malnutrition with a high Malnutrition Inflammation Score (MIS) (Table). He had early satiety. Oral nutrition supplements failed. Albumin was low for many years prior to starting PD. Using one daily exchange (1500 mL) IPN (1% amino acid solution with 1.43% dextrose providing 12 gm amino acids), significant improvements in his MIS and albumin levels followed (Figure). Quality of life including energy level, improved.

Discussion: The management of any chronic disease must include ongoing nutritional assessment and the implementation of nutrition enhancing intervention therapies. Improving nutritional status improves outcomes. The use of IPN in a PD patient with complex congenital heart disease improved markers of inflammation and nutritional status. In conclusion, IPN contributes to long-term improvement of the nutritional status in malnourished PD patients.

Malnutrition Inflammation Score (Scores >8 = severe malnutrition)

Month	MIS Score
May 2022	14
January 2023	9

PUB307

Chyluria Presenting as Milky Urine with Nephrotic Range Proteinuria: A Case Report

Kiran Munir, Abhishek Nimkar, Susana Hong. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: The classical appearance of milky white urine is caused by a fistulous communication between the lymphatic system and the urinary tract resulting in chyle in the urine, known as chyluria. The etiology of chyluria can be divided into parasitic and non-parasitic causes including but not limited to malignancy, lymphatic malformation, and abscess. We present a case of a 67-year-old male who presented with chyluria and nephrotic range proteinuria.

Case Description: A 67-year-old male with history of longstanding diabetes mellitus came to the office for milky white urine and known proteinuria for the past one year associated with ~10lbs weight loss in the last six months. Previous workup included a spot urine protein-creatinine ratio (UPCR) of 7.3g and a urinalysis significant for glucosuria, hematuria, proteinuria but negative for leukocyte esterase. His lipid panel was within normal limits. Computerized tomography scan of the abdomen revealed non-obstructing bilateral renal calculi but was negative for mass effect or hydronephrosis. The patient had a thorough infectious disease workup which was unremarkable. Kidney biopsy revealed normal tubules and interstitium with mild arterial sclerosis. The immunofluorescence and electron microscopy were negative for immune complex and deposits. The patient was then evaluated by urology and a diagnostic lymphaticscintigraphy was negative for lymphatic-urinary fistula. Hence, cystoscopy was pursued which revealed chyluria from the left ureteral orifice. Patient had complete resolution of proteinuria and hematuria post laparoscopic nephrolysis.

Discussion: Chyluria generally indicates the presence of abnormal communication between intestinal lymphatics and urinary tract. Patients with chyluria typically present with milky white urine and the urine chemistry usually shows heavy protein and moderate blood but remains negative for leukocyte esterase. Further evaluation of such a patient includes a thorough history, physical exam, extensive infectious lab work, and further radiologic testing. Urologic intervention with cystoscopy can be useful to lateralize the chyluria. Nephrolysis may be indicated for complete resolution of chyluria.

PUB308

Relationship Between Sarcopenia and Decreased Oral Function in Japanese Patients Undergoing Hemodialysis

Junko Ishida,[1] Masako Tanaka,[1] Nao Muramoto,[1] Teppei Matsuoka,[2] Kenzo Mouri,[2] Ai Asano,[2] Mayumi Yamada,[2] Akihiko Kato.[3] *[1]Kinjo Gakuin University, Nagoya, Japan; [2]Taiseikai Medical Clinic, Ogaki, Japan; [3]Hamamatsu University Hospital, Hamamatsu, Japan.*

Background: Dialysis patients are progressively aging in Japan. Sarcopenia is a systemic condition that leads to loss of muscle mass and strength with age; when exacerbated, it leads to frailty and death. The primary stage of frailty is also associated with a decline in oral functions; this is called oral frailty. In Japan, oral hypofunction has been covered by the public medical insurance system since 2018. However, there is limited research on oral hypofunction in patients undergoing dialysis. Therefore, the present study examined the relationship between sarcopenia, oral hypofunction, and nutritional status in patients undergoing hemodialysis.

Methods: A total of 112 patients (77 men and 35 women) who had undergone hemodialysis were included in the study. The patients were classified into sarcopenia and non-sarcopenia groups based on the Asian Working Group for Sarcopenia (AWGS) 2019 index and examine associated with oral function, nutritional status, and blood levels. The diagnosis of decreased oral function was based on the presence of three or more of seven diagnostic items. Nutritional assessment utilized the Protein Energy Wasting (PEW) index, the Nutritional Risk Index for Japanese Hemodialysis patients (NRI-JH), and the Geriatric Nutritional Risk Index (GNRI). This study was approved by the Institutional Ethics Committee of Kinjo Gakuin University, and was supported by JSPS KAKENHI.

Results: Thirty-nine patients (34.8%) were diagnosed with sarcopenia. The sarcopenia group was significantly older and had significantly lower blood urea nitrogen, creatinine, and dry weight ($p<0.05$). Nutritional risk indices (PEW, NRI-JH, and GNRI) were significantly lower in the sarcopenia group ($p<0.05$) than in the non-sarcopenia group. Furthermore, the sarcopenia group exhibited significantly lower scores in terms of oral dysfunction, specifically the number of remaining teeth, tongue and lip motor functions, and tongue pressure ($p<0.05$).

Conclusions: Blood biochemistry tests showed that the sarcopenia group had low levels of blood urea nitrogen and creatinine; the group was also older and showed low dry weight. The sarcopenia group also had a higher risk of malnutrition according to all assessment methods. Regarding oral function, diagnostic items related to muscle mass and strength showed significantly lower scores.

PUB309

Phosphate Levels as Predictors of Muscle Strength Assessed by Handgrip Strength

Dror Ben Noach,[1] Dina Levy,[1] Michal A. Raz,[1,2] Hila Soetendorp,[1,2] Orit Kliuk Ben Bassat.[1,2] *[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Hyperphosphatemia is common among dialysis patients. Although considered a major risk factor for cardiovascular mortality in patients with chronic kidney disease, the interaction between serum phosphate level and survival in dialysis patients has a U-shape configuration, with increased mortality either with low (less than 4.0 mg/dL) or high (above 5.5 mg/dL) phosphate level. Dietary phosphate restriction may result in undesirable protein restriction and malnutrition in dialysis patients. We aimed to assess the correlation between serum phosphate level and muscle strength, assessed by handgrip strength (HGS).

Methods: A single-center prospective observational study, comparing HGS to various biochemical parameters in chronic hemodialysis (HD) patients. Primary endpoint was the correlation between phosphate level and HGS, measured using a Handgrip Dynamometer in the dominant hand before dialysis session. To avoid bias of phosphate urinary loss, only patients with urinary output less than 200ml/24 hours were included. HGS cutoffs for low muscle strength were defined as <27 kg in men and <16 kg in women. Clinical and biochemical parameters, daily protein consumption assessed by protein catabolic rate (PCR) and dialysis adequacy were compared.

Results: Forty HD patients were recruited and included in the analysis. Median age 75.5 years (IQR 64-83), 15 females (37.5%), median dialysis vintage 43.5 months (IQR 27.25-80.25). Median HGS was 23 for men (IQR 20-29) and 16 for women (IQR 10.7-23). Overall, 17 patients (42.5%) had normal muscle strength while 23 (57.5%) were defined with low muscle strength. Spearman's test demonstrated a significant correlation between normal HGS and lower creatinine (p=0.017), and a trend with younger age (p=0.066) and lower phosphate level (p=0.058). There was no correlation between PCR to HGS or phosphate level. On logistic regression, only younger age predicted normal HGS (p=0.023).

Conclusions: Higher phosphate level did not correlate with higher HGS, nor with higher protein intake. Considering hyperphosphatemia may result from inadequate dialysis, low compliance to phosphate binders or dietary choices, it may not reflect protein intake reliably. Furthermore, it is plausible that high protein consumption is insufficient to enhance muscle strength in dialysis patients.

PUB310

A Classification of Lipids and Lipoproteins in Cardiovascular Diseases

Shruti Bhargava,[1] Sofia de la Puente Secades,[1] Vera Jankowski,[1] Joachim Jankowski.[1,2] [1]*Universitatsklinikum Aachen, Aachen, Germany;* [2]*Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: With imbalances of lipids and lipoproteins being significant contributors to the development and advancement of cardiovascular disease (CVD), there is a growing recognition of the importance of categorizing them according to their mechanistic influence on CVD. This classification is crucial for the identification of novel approaches for predicting and treating CVD. Hence, there is a pressing requirement for a fresh lipid classification system that takes into account their specific impact on cardiovascular health.

Methods: To advance our understanding of the role of lipids and lipoproteins in cardiovascular disease (CVD), it is essential to reclassify them based on their specific mechanistic impact, rather than relying solely on their traditional classification according to biological functions. In light of this, we classified lipids and lipoproteins into three distinct groups: (i) those that enhance CVDs, (ii) those with a conditional impact on CVDs, and (iii) those with no known effect on CVDs due to insufficient evidence.

Results: Low density lipoprotein, very low density lipoprotein, lipoprotein (a), triglycerides, trans-fatty acids, phosphatidylcholine, and lysophosphatidic acid have a strong impact on thrombosis and atherosclerosis. High density lipoprotein, fatty acids, sphingolipids andphospholipids have a conditional impact on CVD progression based on based on factors such as oxidation, presence of cofactors, and plasma concentration of other lipids. Due to lack of evidence in existing literature proving their impact on CVD risk or events, biologically active lipids such as mono- and diglycerides, prenol lipids, stearic acids, galactolipids, sterols, glycolipids, and sulpholipids are placed in this category, implying that these lipids are essential for biological functions but do not have known impact on the onset or progression of CVD.

Conclusions: By this novel classification of lipids and lipoproteins we identify the intersecting mechanisms by which lipids that enhance CVDs cause genesis and progression of CVDs is important to discover new therapeutic avenues.

PUB311

Pathophysiological Insights and Therapeutic Options for Cardiovascular Disease in CKD

Joachim Jankowski.[1,2] [1]*Universitatsklinikum Aachen, Aachen, Germany;* [2]*Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: Patients with chronic kidney disease (CKD) are at an increased risk of cardiovascular complications, including coronary artery disease, heart failure, arrhythmias, and sudden cardiac death. The incidence and prevalence of cardiovascular events are already higher in patients with early CKD stages (CKD stages 1-3) compared to the general population, but the risk significantly escalates in patients with advanced CKD stages (CKD stages 4-5). In fact, cardiovascular disease surpasses end-stage kidney disease (CKD stage 5) as the leading cause of death in this high-risk population. CKD induces a chronic proinflammatory state throughout the body, leading to vascular and myocardial remodeling processes.

Methods: The information presented in this article is based on a comprehensive review of existing literature related to cardiovascular disease in patients with CKD. Relevant studies, research articles, and clinical data were collected from various databases and sources. The selected information focuses on the pathophysiology, clinical consequences, and underlying mechanisms of cardiovascular disease in CKD.

Results: Patients with CKD face an elevated risk of cardiovascular complications, with cardiovascular disease being the leading cause of mortality in this population. CKD contributes to a systemic proinflammatory state that drives vascular and myocardial remodeling processes. These processes give rise to atherosclerotic lesions, vascular calcification, vascular senescence, myocardial fibrosis, and cardiac valve calcification. The cardiovascular manifestations in CKD resemble an accelerated aging process, further exacerbating the cardiovascular risk.

Conclusions: The understanding of cardiovascular disease in CKD is crucial due to its high prevalence and impact on patient outcomes. The systemic proinflammatory state induced by CKD contributes to significant vascular and myocardial alterations, leading to various cardiovascular complications. Recognizing the accelerated aging effect on the cardiovascular system in CKD patients is essential for effective management and the development of preventive strategies. Further research is warranted to explore novel therapeutic approaches and interventions targeting cardiovascular disease in CKD.

Systolic Blood Pressure in CKD Grades 4-5 and Risk of Kidney Replacement Therapy and Mortality

Jonathan Chavez,[1] Bladimir Diaz Villavicencio,[1] Clementina Elizabeth Calderon Garcia,[1] Manuel Arizaga Napoles,[1] Ana E. Oliva,[1] Frida Margarita de la Vega Méndez,[1] Francisco Gonzalo Rodríguez García,[1] Juan Gómez Fregoso,[1] Guillermo Navarro Blackaller,[1] Ramon Medina,[1] Maria de la Luz Alcantar Vallin,[1,2] José David G. Barajas.[1,2] [1]*Hospital Civil de Guadalajara, Guadalajara, Mexico;* [2]*Universidad de Guadalajara, Guadalajara, Mexico.*

Background: In patients with chronic kidney disease grade 4 and 5 (CKD G4-5) without dialysis and arterial hypertension, it is unknown if the values of systolic blood pressure (SBP) considered in control <120 mmHg are associated with kidney replacement therapy (KRT) and mortality.

Methods: In a retrospective cohort study, hypertensive CKD G4-5 patients attending the Renal Health Clinic at the Hospital Civil de Guadalajara were enrolled. We divided them into those that achieved SBP < 120 mmHg (controlled) and those who did not (>120 mmHg), the uncontrolled. Our primary objective was to analyze the association between the controlled group and KRT; the secondary objective was the mortality risk, and if there were subgroups of patients that achieved more benefit.

Results: A total 275 hypertensive CKD G 4-5 patients were included, 62 in the controlled and 213 in the uncontrolled group; mean age 61 years, SBP was lower in the controlled group (111 mmHg) compared to the uncontrolled group (140 mmHg), eGFR was similar (20.41 ml/min/1.73m^2). There was a tendency to increase the mortality risk in the uncontrolled group (OR 6.4, p= 0.082) and an association by the Kaplan-Meir analysis (Log-rank p= 0.043). The subgroup analysis for risk of KRT in the controlled group revealed that patients ≥ 61 years had a lower risk of KRT (OR 0.87, p=0.03, p of interaction = 0.005), but no differences were found in the subgroup analysis for mortality. Before propensity score matching, no association was found in the risk of KRT in a multivariate analysis.

Conclusions: In a retrospective cohort of patients with CKD G4-5 and hypertension, SBP >120 mmHg was not associated with risk of KRT but could increase the risk of death.

Table 2. Incidence rate of kidney replacement therapy and death according to systolic blood pressure groups.

Group	Patient - year	Events	Rate (1000 patient - year)	LIC	UIC
Kidney replacement therapy					
Controlled	92.27	8	86.69	43.35	173.35
uncontrolled	295.87	26	87.87	59.83	129.06
Total	388.15	34	87.59	62.56	122.59
Mortality					
Controlled	109.44	1	9.13	1.28	64.86
uncontrolled	296.27	14	47.25	27.98	79.78
Total	405	15	36.97	22.28	61.32

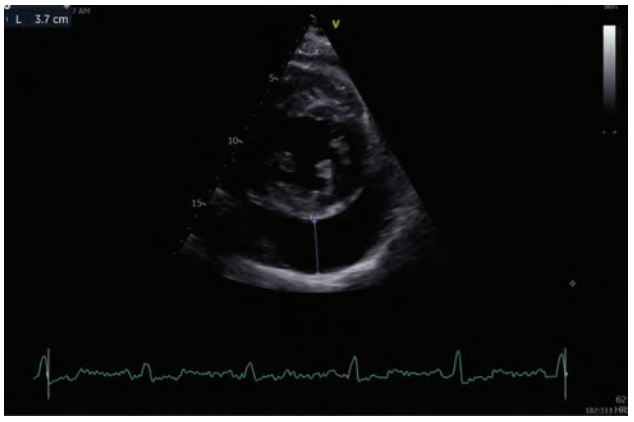
Minoxidil-Related Pericardial Effusion in a Renal Transplanted Patient

Bahram Hashemi Dam,[1,2] Joanna Delekta,[1] Laura Vakili Jensen,[2] Sam Riahi.[1,2] [1]*Aalborg Universitetshospital, Aalborg, Denmark;* [2]*Aalborg Universitet, Aalborg, Denmark.*

Introduction: Minoxidil is used in patients with inadequate response to conventional antihypertensive treatment. It causes vasodilation by opening adenosine triphosphate-sensitive potassium channels. A serious side effect of minoxidil is fluid retention. Multiple case reports have shown minoxidil-induced pericardial effusion in dialysis patients; yet none has been published in a kidney transplanted patient.

Case Description: A 49-year-old man with type 1 diabetes mellitus and renal transplantation in 2014, with stable renal allograft dysfunction (serum creatinine about 1.7 mg/dl) was treated for resistant hypertension with amlodipine, ramipril, furosemide, metoprolol and minoxidil. From March to July 2021, he was admitted four times at the Department of Cardiology due to exertional dyspnea and palpitations. Physical examinations revealed noticeable pericardial friction rub and subtle peripheral edema, otherwise he was hemodynamic stable. Echocardiography showed normal left ventricle ejection fraction, mild ventricular hypertrophy, no valvular dysfunction and nor pulmonal hypertension. Large pericardial effusion, up to 3.7 cm posterolateral to the left ventricle was visualized (Figure). There was no sign of tamponade; but due to large amount of fluid the patient underwent pericardiocentesis where 1700ml was drained. Analysis revealed a transudate fluid without infectious, malignant or inflammatory characteristics. His renal allograft function was stable and near normal. Attention was then paid towards minoxidil toxicity. It initiated 6 months before the first pericardial effusion. Minoxidil was discontinued upon the discharge from the hospital in July 2021. Total resolution of pericardial effusion was observed on control echocardiography after one month.

Discussion: Minoxidil-induced pericardial effusion occurs in about 3% of patients. It can also be idiosyncratic, such as our case with otherwise uneventful post-transplant period. Though, ruling out other causes is essential.



PUB314

Analysis of the Kidney-Heart Cross-Talk Using Computation Ecosystems

Vera Jankowski,[1] Shruti Bhargava,[1] Zhuojun Wu,[1] Joachim Jankowski.[1,2] *[1]Universitatsklinikum Aachen, Aachen, Germany; [2]Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: Over the past 50 years, there has been extensive research focused on identifying mediators and understanding molecular processes involved in physiological, pathophysiological, and correlation-based studies within individual organs like the kidney or heart. The organ-centered approaches are valuable for addressing specific research questions, but, they are insufficient, failing to provide a comprehensive understanding of disease progression. The interconnectedness and multidimensional correlations that exist within complex biological systems are often overlooked within the framework of these approaches. Therefore, there is a growing recognition of the need to adopt a more holistic and multilevel approach that integrates various factors and dimensions to gain a more accurate and complete understanding of disease processes.

Methods: Holistic approaches to understanding multimorbid diseases involve integrating, merging, and correlating extensive, diverse, and multidimensional data from various sources, including -omics and nonomics databases. The importance of holistic approaches has grown significantly in comprehending and revealing intricate interactions and molecular overlaps between diverse organ systems in the pathophysiology of systemic diseases such as cardiorenal syndrome. The objective of these approaches is to develop practical and applicable disease models through the utilization of mathematical, statistical, and computational tools, thus establishing initial computational ecosystems.

Results: Holistic approaches help gain deeper insights into complex diseases by considering multiple dimensions and facilitating the translation of findings into clinical applications. Effectively addressing the intricacies of multimodality and multimorbidity requires data-driven scientific approaches that extend beyond the existing capabilities and necessitate multiphased and cross-sectional methodologies. These approaches aim to deconstruct complexity by tackling smaller, more manageable challenges.

Conclusions: We provide an overview of the existing understanding regarding the interconnection between the kidney and heart, known as kidney-heart crosstalk. Additionally, we explore the methodologies and prospects that emerge from the innovative utilization of computational ecosystems, enabling a comprehensive analysis of this interplay between the kidney and heart.

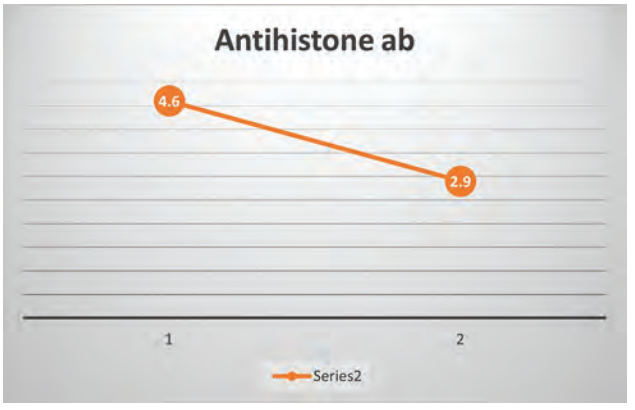
Anti-Histone Antibodies Associated with a Hydralazine-Induced Rash

Parker Lehmann,[1] Udayan Y. Bhatt,[2] Nancy J. Smith,[3] Asish Thakkar.[3] *[1]Idaho College of Osteopathic Medicine, Meridian, ID; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]VA Central Ohio Healthcare System, Columbus, OH.*

Introduction: Hydralazine is used in the treatment of hypertension and heart failure. It's side effect profile includes Hydralazine-Induced Lupus (HIL). Typical manifestation of HIL include arthralgias, serositis, myalgias, and a malar rash. It is serologically associated with anti-histone antibodies (Anti-HisAb) and a + antinuclear antibody (ANA).

Case Description: The patient is a 50yo male with a history of hypertension. Management of his hypertension has been complicated by many drug sensitivities. His regimen consisted of nifedipine, hydralazine, and carvedilol. It had been stable for over 2 years. The patient developed a new-onset rash consisting of diffuse erythematous papules with excoriations. He denied any new medications, lotions, clothing, or other new exposures. The patient underwent a punch biopsy which showed eczematous dermatitis with eosinophils. This was thought to be diagnostic of allergic contact dermatitis, spongiotic drug eruption, and atopic dermatitis. The rash improved with cotricosteroids but it returned after discontinuation of steroids. Serologies showed a +ANA but a negative anti-double stranded deoxyribonucleic acid antibody (Anti-dsDNA). Given the hydralazine and +ANA, an Anti-HsAb was checked, despite the lack of classic HIL symptoms (including the classic rash) and negative dsDNA. This returned positive. Because of the recurrent rash and the + Anti-HisAb, hydralazine was stopped. The patient experienced an improvement in his rash and a reduction in his Anti-HisAb titer (see figure).

Discussion: Drug rashes are very common in many drug classes. This case is unique in that the patient did not have the classic rash or other symptoms of HIL but had + Anti-HisAb. There are case of reports of lupus being associated with atopic dermatitis (which was noted on biopsy) but this is an atypical finding. This report supports the contention that patients on hydralazine should be serologically evaluated for HIL should evidence of drug reactions occur, despite a lack of classic symptoms.



PUB316

Efficacy of Cardiac Synchronization Therapy for Patients with ESRD and Chronic Heart Failure

Guiling Wei, Bing Zhuang, Yuan Luo, Hong Ye, Hongdi Cao, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To evaluate the efficacy and safety of cardiac resynchronization therapy (CRT) in CKD patients complicated with chronic heart failure.

Methods: 4 Patients who received CRT implantation from January 2019 to June 2022 in Center for Kidney Disease,2nd Affiliated Hospital of Nanjing Medical University were admitted. CRT is recommended for symptomatic patients with HF with Left ventricular ejection fraction (LVEF)≤40%, QRS duration≥150m, and LBBB QRS morphology despite OMT. The clinical data, electrocardiogram, echocardiography and cardiac function screening were collected.

Results: Patients (average age of 62.3±7.9 years) were followed up for 19.7±9.9 months. The dialysis age was 76.2 (27.3,79.0) months. Patients were implanted with CRT, the QRS duration (183.3±26.3 Vs 150.0±13.0ms), left ventricular end-diastolic diameter LVEDD (70.3±10.3 *vs* 64.0±11.1 mm), left ventricular end-systolic diameter LVESV (57.8±13.2 *vs* 48.8±15.7mm), and pro-BNP [167459.5 (59645.8, 231789.0) ng/ml *vs* 81773.0 (26151.3, 134313.0) ng/ml were decreased, the decline rates were respectively 18.2%, 9.0%, 15.6%, 25.1% and 51.2%. The LVEF (32.8±7.4 *vs* 42.3±15.3%) was improved by 30.0%. The cardiac function status was improved. None could tolerate 6 min walking test before operation. The average distance of 6min walking test in 3 patients was (328.3 ±138.2) meters one year after operation.

Conclusions: CRT improves left ventricular function and quality of life in uremic patients with chronic heart failure, and none of serious side effects were observed.

PUB317

Beneficial Markers for Renal Prognosis in Hypertensive Emergencies with Severe Renal Dysfunction

Rei Nakazato, Akiko Mii, Yukinao Sakai. *Nihon Ika Daigaku Fuzoku Byoin, Bunkyo-ku, Japan.*

Background: Hypertensive emergencies are poor prognosis conditions associated with rapid blood pressure (BP) elevation and various organ damage. The frequency of dialysis induction due to nephrosclerosis is high and early detection and appropriate therapeutic intervention is important.

Methods: We selected 15 patients diagnosed as hypertensive emergencies with severe renal dysfunction (serum creatinine level > 2.5mg/dL) admitted to our hospital over the past 14 years. These were divided into two groups: those who received renal replacement therapy (RRT, n=9) after 3 years and those who were not received (non-RRT, n=6). The clinical features and laboratory data were reviewed and compared retrospectively.

Results: The median age was 48 years old and the male to female ratio was 3:1. All the patients lacked medical examination and regular checkups after diagnosis of hypertension. 33% of them were obese with a body mass index > 25. On admission, about 80% had elevated plasma renin activity and serum aldosterone levels, while there were no cases of renal artery stenosis. Between the two groups, there was no significant difference in serum creatinine levels. Serum LDH levels in the non-RRT group were higher than those in the RRT group. Serum potassium levels and platelet counts were lower, respectively. These data at post-antihypertensive treatment was improved significantly in

the non-RRT group. Serum values of LDH, potassium, and platelet in the comparison of pre-and post-treatment data of the two groups showed significantly improved by two-way analysis of variance.

Conclusions: In our study, there were young or middle-aged adults and some of them were obese. Therefore, taking health-checkup is helpful for the prevention of the risk of hypertension and appropriate treatment. Higher LDH levels and decreased platelet counts in the non-RRT group suggested the development of severe endothelial damage with rapid BP elevation in the short term. Severe renal dysfunction in these cases can be improved by appropriate antihypertensive therapy. Furthermore, the lower potassium level suggested the aggravation of the renin-angiotensin-aldosterone system (RAAS) and early induction of RAS inhibitors would be beneficial for the maintenance of BP and renal protection. In conclusion, serum LDH, platelet count, and serum potassium would be useful predictors of renal prognosis.

PUB318

A Case of Primary Hyperaldosteronism with Hypomagnesemia

Sriram Sriperumbuduri, Pradeep Vaitla, Mohammad Atari, Bushra Syed, Sanjana Kapoor. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Primary hyperaldosteronism classically involves a hypertensive patient with spontaneous or diuretic induced hypokalemia and metabolic alkalosis. We describe one such patient with hypomagnesemia and hypocalcemia along with the classic features.

Case Description: 51 year-old male, presented for management of 20-year history of hypertension (HTN). He has history of type 2 diabetes mellitus and coronary artery disease. Labs showed serum creatinine of 1.3 mg/dl, low serum potassium at 2.8 mmol/l, metabolic alkalosis with serum bicarbonate at 30 mmol/l, low serum magnesium at 1.2 mg/dl and low serum calcium at 7.9 mg/dl (serum albumin of 4.2 mg/dl). Fractional excretion of potassium (22.4%) and magnesium (4%) were high. Parathyroid hormone was appropriately elevated at 98.6 pg/ml and 25-O vitamin D level was mildly low at 16.2 ng/ml. Primary hyperaldosteronism was suspected due to hypokalemia and metabolic alkalosis. Random plasma renin activity was low at 0.10 ng/ml/hr (normal range- NR: 0.25-5.82 ng/ml/hr) and aldosterone was normal at 11 ng/dl (NR: <= 21 ng/dl) with elevated aldosterone: renin ratio at 110 (NR: 0.9-28.9). He was started on oral potassium and magnesium supplementation, and spironolactone was prescribed at 25 mg daily. Repeat laboratory values after 2 weeks showed normal serum potassium at 4 mmol/l. 24-hour urine electrolytes at this time showed sodium of 241 mmol, potassium of 78 mmol and a high calcium at 445 mg (NR: <300 mg). Plasma aldosterone: renin ratio remained elevated at 147 even after correcting the serum potassium. Computerised tomography scan of the abdomen with intravenous contrast showed a 1.2 cm right adrenal adenoma with normal left adrenal gland. Dose of spironolactone was increased to 50 mg daily. His home blood pressures remained controlled at 135/80 mm of Hg. A diagnosis of primary hyperaldosteronism secondary to unilateral adrenal adenoma was made with further plan to do adrenal vein sampling and adrenalectomy as appropriate.

Discussion: The case highlights a rare presentation of primary hyperaldosteronism with magnesium and calcium wasting, mimicking Gitelman's syndrome. Aldosterone escape could potentially decrease sodium reabsorption at the thick ascending limb of Henle, which in turn leads to poor magnesium reabsorption. Consequent hypomagnesemia leads to calcium wasting due to PTH resistance at the level of thick ascending limb.

PUB319

Anti-Müllerian Hormone and Cardiovascular Risk in Males with CKD: Preliminary Findings from a Cross-Sectional Study

Nicole Larsen, Victoria J. Riehl-Tonn, Sofia B. Ahmed, Tyrone Harrison, Shu Foong, Darlene Y. Sola, Daniel Kong, Sandi M. Dumanski. *University of Calgary, Calgary, AB, Canada*.

Background: Cardiovascular (CV) disease is the leading cause of death for people living with chronic kidney disease (CKD), and this risk is higher in males. Reduced Anti-Müllerian Hormone (AMH), a reproductive hormone involved in male fertility, is a common complication of CKD and is associated with increased CV risk in males in the general population. However, the relationship between AMH and CV risk in males living with CKD remains unknown. Our study aims to estimate the association between AMH and arterial stiffness, a validated predictor of CV risk, in males living with CKD.

Methods: A cross-sectional study was completed in males living with CKD recruited from Calgary, Alberta, Canada. We collected basic demographic and comorbidity data. Serum AMH levels were measured using a validated immunoassay. Using standardized protocols, we assessed pulse wave velocity (PWV) and aortic augmentation index (AIx) with applanation tonometry to determine arterial stiffness. Mean Arterial Pressure (MAP) was calculated using systolic and diastolic blood pressure measurements which were collected using standardized protocols. Multiple linear regression analyses were used to estimate the association between AMH and each measure of arterial stiffness, as well as MAP.

Results: Nine males living with CKD were included (age 42 ± 11 years, estimated glomerular filtration rate 76 ± 25 ml/min/1.73m^2). A trend towards a negative association between AMH and AIx was demonstrated ($R^2 = 0.41$, $p = 0.06$), though no association was observed between AMH and PWV ($R^2 = 0.05$, $p = 0.57$).

Conclusions: AMH levels are not significantly associated with increased arterial stiffness in males living with CKD, though it is likely that our sample is underpowered to detect a significant association. Given the high CV risk of males with CKD, further investigation into this potential CV risk factor is warranted.

Impact of Impaired Kidney Function in the Mortality of Patients with Chagas Disease Submitted to Cardioverter-Defibrillator Implant

Fernanda M. Tapioca,[1,2] Maria G. Guimaraes,[1,3] Luiz C. Passos.[1,2] *[1]Hospital Ana Nery, Salvador, Brazil; [2]Universidade Federal da Bahia, Salvador, Brazil; [3]Hospital da Bahia, Salvador, Brazil*.

Background: Data on kidney disease impact in HFrEF due to Chagas Disease (CD) is limited in the current literature. Unlike other causes of HFrEF, CD may have such a high disease burden that it overshadows other comorbidities. We performed a prospective study to access if an impaired glomerular filtration rate (eGFR) had an association with mortality and survival rates in patients with CD submitted to cardioverter-defibrillators (ICD) implant.

Methods: We collected data on 141 patients with CD that implanted ICD between 2017 and 2020. An altered kidney function was considered with an eGFR < 60 mL/min. An analysis for the survival rate between the groups was made with the Log Rank test. Multivariable logistic regression was used to identify predictors of death. Statistical analysis was done through SPSS, v.25, and significance level was set in 5% ($p<0.05$).

Results: Baseline characteristics are reported on Table 1. The median follow-up was 563 days. Patients in both groups had similar prescriptions regarding use of triple therapy for HFrEF (p=0.77). During the study, 52 patients died; 47.7% patients had altered kidney function and 32% with normal eGFR. In a univariate analysis for the outcome of death, the presence of a lower eGFR was not statistically significant (p=0.07). In the analysis for the survival rates, there was no difference between them (p=0.06). In a binary logistic regression model, a greater chance of death was not associated with a change in eGFR in these patients [p=0.227 (OR 1.69; CI 95% 0.721-3.959)].

Conclusions: In our study, in a group of patients with HFrEF due to Chagas cardiomyopathy using ICD, with similar patterns of disease modifying drugs, there was no significant association between kidney function and mortality.

Table 1. Baseline characteristics of the patients

	eGFR < 60 ml/min (n = 44)	eGFR ≥ 60 ml/min (n = 97)	P value
Male (%)	19 (43.2)	63 (64.9)	0.015
Age (± SD)	62.7 (9.34)	57.3 (11.26)	0.006
Diabetes (%)	13 (29.5)	18 (18.6)	0.144
Atrial fibrillation (%)	19 (43.2)	29 (29.9)	0.123
Maggic SCORE (IQR)	17.5 (12.2-31.1)	12.2 (7.7-20.3)	0.001
Ejection fraction (IQR)	28 (23.2-33.7)	29 (23.5-35)	0.375
eGFR* (IQR)	47 (37.2-53.7)	83 (70-98)	< 0.001

eGFR - estimated by the CKD-EPI 2021 equation; IQR – interquartile range.

Hyperfiltration, Metabolic Syndrome, and Risk of Adverse Clinical Outcomes

Dae Kyu Kim,[1] Yu ho Lee,[2] Jin sug Kim,[1] Yang Gyun Kim,[3] Su Woong Jung,[3] Ju young Moon,[3] Kyunghwan Jeong,[1] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Hospital, Seoul, Republic of Korea; [2]CHA Bundang Medical Center, Seongnam, Republic of Korea; [3]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea*.

Background: Glomerular hyperfiltration and metabolic syndrome increase the risk of cardiovascular disease and all-cause mortality. While hyperfiltration is strongly related to the metabolic risk, it is little known how the combined association of these two factors affects the risk of metabolic syndrome-related complication, CV disease and all-cause mortality.

Methods: We reviewed the National Health Insurance Service database of Korea for people who received national health screenings between 2009 and 2011. Hyperfiltration (n = 199,807) was defined as eGFR >95th percentile after stratification for age, sex, height and weight and normal filtration as eGFR 25-75th percentile (n = 2,376,489). Metabolic syndrome was considered as the presence of three or more of the metabolic risks. Individuals were compared based on the presence of hyperfiltration and metabolic syndrome

Results: Compared to normal filtration without metabolic syndrome, co-existence of glomerular hyperfiltration and metabolic syndrome was associated with the greatest risk of hypertension, diabetes and cardiovascular event. Hyperfiltration without metabolic syndrome also increased the risk of diabetes (HR 1.22, 95% CI 1.18-1.27) and hypertension (HR 1.06, 95% CI 1.04-1.07), but it was not associated with higher risk of cardiovascular event (HR 1.04, 95% CI 0.99-1.09). among four categorized individuals, the risk of all-cause mortality increased highest in those who had hyperfiltration without metabolic syndrome (HR 1.22, 95% CI 1.17-1.28) and there was a significant interaction between hyperfiltration and metabolic syndrome in association with all-cause mortality (P for interaction = 0.003).

Conclusions: Our findings indicate that glomerular hyperfiltration was significantly associated with higher risk of hypertension and diabetes, even in the absence of metabolic syndrome. Notably, hyperfiltration without metabolic syndrome was more detrimental to mortality than that with metabolic syndrome.

PUB322

Dapagliflozin in Patients with Low and High uACR

Navdeep Tangri,[1] Maria K. Svensson,[2] Johan Bodegard,[3] Samuel Adamsson Eryd,[3] Marcus Thuresson,[4] Tadashi Sofue.[5] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Department of Medical Sciences, Renal Medicine, Uppsala University, Uppsala, Sweden; [3]CVRM Evidence, BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden; [4]Statisticon AB, Uppsala, Sweden; [5]Department of Cardiorenal and Cerebrovascular Medicine, Kagawa University, Kagawa, Japan.*

Background: We explored clinical outcomes in new users of dapagliflozin 10 mg with low urine albumin to creatinine ratio (uACR; 30–200 mg/g) and high uACR (≥ 200 mg/g) in patients with chronic kidney disease (CKD), with and without type 2 diabetes (T2D).

Methods: This study used claims data from the USA between 2021 and 2022. Patients with and without T2D who were new users of dapagliflozin 10 mg were indexed at treatment start and grouped according to baseline uACR (low or high). Patients on dialysis or immunosuppressive drugs or with polycystic kidney disease or stage 5 CKD were excluded. Incidence of hospitalization for cardiorenal events (CKD or heart failure) and atherosclerotic cardiovascular diseases (ASCVD) were compared separately within non-T2D and T2D populations using age- and sex-adjusted survival regression.

Results: In non-T2D patients, 332 (54%) new users of dapagliflozin had low uACR and 286 (46%) had high uACR. Corresponding numbers for patients with T2D were 1987 (53%) and 1741 (47%). New users of dapagliflozin with low and high uACR had similar baseline characteristics, both with and without T2D. In non-T2D patients, event rates for cardiorenal hospitalizations were similar in the low and high uACR groups (8.3 and 9.2 per 100 patient-years, respectively). There was no significant risk difference between low and high uACR (hazard ratio [HR] 1.16, 95% confidence interval [CI] 0.54–2.49; Figure). Similar results were seen in patients with T2D (HR 0.92, 95% CI 0.68–1.24). In contrast, the risk of ASCVD was significantly higher in patients with high uACR versus low uACR (HR 1.67, 95% CI 1.03–2.72).

Conclusions: Dapagliflozin's beneficial effect on cardiorenal risks appeared similar in patients with low and high uACR independent of T2D. ASCVD risk remained higher in high versus low uACR patients. These findings suggest cardiorenal effectiveness of dapagliflozin in patients with CKD and low uACR, without T2D.

Urinary Features Predict Cast Nephropathy

Richard E. Wing, Shamsul Hasan, Daniel Rechlin, Jerome L. Jean-Gilles. *University of Rochester Medical Center, Rochester, NY.*

Introduction: Multiple Myeloma may present with a constellation of features including back pain, anemia, hypercalcemia, renal failure, and bland urine sediment. A multitude of findings are possible on biopsy most commonly including cast nephropathy, al amyloidosis, monoclonal immunoglobulin deposition disease, and tubular injury. Urinary characteristics may predict biopsy findings.

Case Description: A 63 year old woman former smoker presented with two years of progressive backpain treated with NSAIDs. Plain films revealed thoracic compression fractures. Select laboratories are summarized in the table. Urine microscopy relevealed a largely intact tubulo-epthelial cast [Image]. A percutaneous renal biopsy was obtained. The light microscopy revealed angulated, fractured casts with associated cellular reaction and tubular injury. A Congo red stain was negative. A paraffin based immunofluorescence showed monoclonal Kappa positivity in the casts. Moderate atherosclerosis and severe interstitial fibrosis were noted. Bone marrow biopsy revealed plasma cell myeloma (90% of marrow cellularity).

Discussion: Urinary findings include a large intact tubular cast, high sodium:creatinine ratio, and large non-albumin proteinuria. All point to a biopsy finding of a cast nephropathy.

Hemoglobin (mg/dL)	9.7
Serum Bicarbonate (mmol/L)	19
Serum Creatinine (mg/dL)	5.5
Serum Calcium (mg/dL)	11.2
Serum Albumin (g/dL)	4.0
Serum Total Protein (g/dL)	6.9
Serum Paraprotein (g/dL)	0.2
Serum Kappa:Lambda ratio	3630

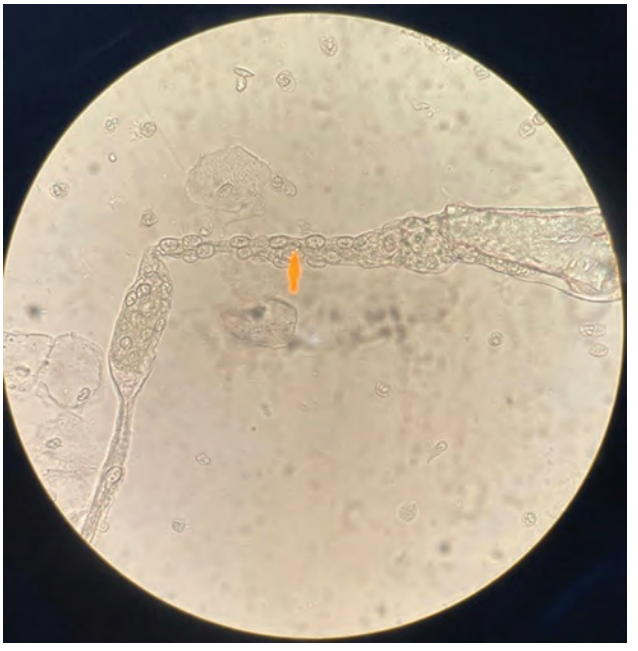
Urine Microalbumin (mg/dL)	<1.2
Urine Creatinine (mg/dL)	36
Urine Sodium (mmol/L)	44



PUB324

When You Hear Hoof Beats, It Can Be a Horse or a Zebra or Both Galloping Simultaneously!

Danish Waqar, Maria M. Picken, Ewa Borys, Kavitha Vellanki. *Loyola University Medical Center, Maywood, IL.*

Introduction: Multiple primary malignancies are defined as two or more malignancies arising independently of one another. While it is not uncommon to have multiple primary malignancies in a life time, simultaneous diagnosis is rare. Here, we present a case of acute kidney injury (AKI) and hypercalcemia, work up of which lead to simultaneous diagnosis of two different primary malignancies.

Case Description: A 74 year old male presented with 2 month duration of abdominal pain, weight loss and poor appetite. He had a large palpable abdominal mass, confirmed on CT imaging as a 13.8 x 13.4 cm mesenteric mass. Laboratory work up revealed AKI (serum creatinine of 5.6 mg/dL) and hypercalcemia (serum calcium of 14.2 mg/dL). Urinalysis was +ve for protein with 24 hour urine protein of 2.5 grams. Mesenteric mass biopsy confirmed our suspicion of lymphoma, final diagnosis being diffuse large B-cell lymphoma (DLBCL). Work of hypercalcemia is shown in Table 1 and kidney biopsy revealed lambda light chain proximal tubulopathy (Figure 1) with subsequent bone marrow biopsy confirming the diagnosis of Multiple Myeloma (MM).

Discussion: Simultaneous occurrence of DLBCL and MM is extremely rare. Our case illustrates the importance of a thorough workup of hypercalcemia despite an obvious cause as both malignancies can present with AKI, hypercalcemia and proteinuria. Workup of hypercalcemia (normal 1, 25 (OH)2 D which is usually elevated in lymphoproliferative disorders and markedly elevated serum lambda light chains) prompted us to a kidney biopsy and diagnose MM simultaneously. Conclusion: Even with a concurrent known cause of hypercalcemia, a full workup for hypercalcemia is always warranted. We like to think "When you hear hoof-beats, it can be a horse or a zebra or both".

Table 1 summarizing the hypercalcemia workup

Hypercalcemia workup	25-hydroxy vitamin D	1,25-Dihydroxy Vitamin D	Intact Parathyroid hormone (iPTH)	Parathyroid hormone related protein (PTHrp)	serum free light chain (kappa)	Serum Free light chain (lambda)	Serum Kappa/Lambda ratio
Result in units (reference range)	28 ng/ml (20-80 ng/ml)	<8 pg/ml (0-8 pg/ml)	7 pg/ml (14-67 pg/ml)	19 pg/ml (11-20 pg/ml)	31.8 mg/L (3.3-19.4 mg/L)	3,117 mg/L (5.7-26.3 mg/L)	0.01 (0.26-1.65)

Safety of Systemic Anticancer Treatment (ST) in Patients with ESKD and Metastatic Renal Cell Carcinoma (mRCC): A Single Institution Experience

Tomaz Milanez,[1,2] Miha Arnol,[2] Janja Ocvirk,[1] Bostjan Seruga,[1] Edgar A. Jaimes.[3,4] *[1]Onkoloski Institut Ljubljana, Ljubljana, Slovenia; [2]Univerzitetni klinicni center Ljubljana, Ljubljana, Slovenia; [3]Memorial Sloan Kettering Cancer Center, New York, NY; [4]Weill Cornell Medicine, New York, NY.*

Background: ST for mRCC is linked to a variety of adverse events (AEs) including bleeding and infections. A significant number of patients with mRCC develop CKD that can progress to ESKD requiring renal replacement therapy. It is not known however whether these patients have an increased risk for bleeding and infections while receiving ST.

Methods: We identified 29 ESKD patients (21 male, 8 female) with mRCC who received ST that included VEFGR/TK inhibitors, immune check point inhibitors (ICI) or mTOR inhibitors alone or in combination at the Institute of Oncology Ljubljana in Slovenia between December 2009 and January 2023. By manual chart review, we determined the frequency and severity of bleeding and infectious AEs in this cohort while on active treatment for mRCC.

Results: The median age for the patients studied was 71 years (range 47-83). At the start of ST, 20 patients were already on chronic hemodialysis (HD). Six patients had eGFR ≤30 ml/min/1.73m^2 and three had a GFR >30 ml/min/1.73m^2 at the start of ST but all patients eventually developed ESKD and were started on chronic HD. Before ST, eight patients experienced a bleeding episode including three who had a gastrointestinal bleed (GIB). Grade 4 epistaxis was seen in three patients, including a patient that developed hemorrhagic shock during first-line treatment with sunitinib. Two patients experienced grade 4 anal hemorrhage, one due to hemorrhoids during first-line therapy with sunitinib. One patient underwent an urgent nephrectomy due to bleeding during treatment with sunitinib and a second patient during pazopanib treatment. In four patients, grade 4 GIB was observed during or after the ST. The cumulative incidence of grade 3/4 bleeding was 0.59 (17 events/29 pts), and 1.4 (40 events/29 pts) for all-grade bleeding. During ST, 10 patients experienced grade 4 infectious AEs. Six developed sepsis, and one, who was in the first cycle of first-line treatment with sunitinib and receiving HD, developed septic shock.

Conclusions: Serious AEs during ST, including bleedings and infections, may be more frequent in mRCC patients with ESKD as compared to the general mRCC population. Clinicians should be aware of this increased risk that may have a significant impact on the duration and selection of ST for these patients.

PUB326

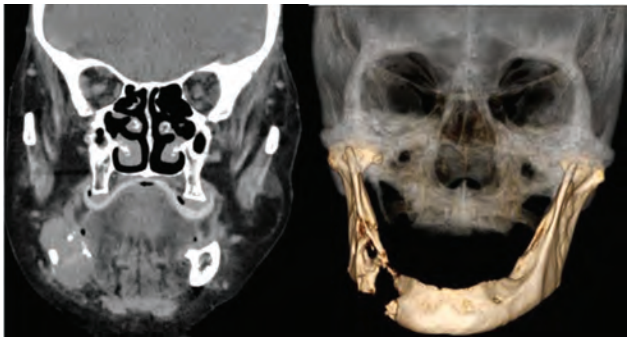
Renal Cell Carcinoma Presenting as Jaw Pain

Matthew T. Mcauliffe, Kostas Papamarkakis. *Baystate Medical Center, Springfield, MA.*

Introduction: Renal Cell Carcinoma (RCC) is the most common renal malignancy. Metastases to bone usually present as osteolytic lesions from T12-L5. This case demonstrates a mandibular mass as the initial presentation of RCC.

Case Description: A 91-year-old female presented with shortness of breath. Medical history was significant for chronic pain for which she took daily oxycodone. She did not smoke. Physical examination revealed a right mandibular jaw mass. No cervical lymphadenopathy, trismus or parotid gland swelling was found. Computed tomography (CT) of the maxillofacial structures demonstrated a 3.5 cm destructive lesion with a displaced pathologic fracture of the right mandibular body. It also showed a large destructive mass at the level of C3 extending into the spinal cord. Biopsy demonstrated renal cell carcinoma. Subsequent CT Abdomen/pelvis revealed a large 8.5 cm multilobulated mass replacing a majority of the right kidney.

Discussion: RCC is the most common solid tumor of the kidney. The classic presenting symptoms are the triad of hematuria, flank pain, and a palpable abdominal mass; however, this presentation only occurs in 10-15% of patients. 25-30% of patients will have metastatic disease at time of presentation. RCC commonly spreads to orofacial soft tissues and sinuses, however, only 1% of patients with RCC demonstrate isolated head and neck metastases. Oral metastases convey a worse clinical prognosis. When multiple osteolytic lesions present in the head and neck, it is strongly recommended that a search for the primary tumor be conducted.



PUB327

Single and Combination Immunotherapy with Chemotherapy and the Risk of AKI in Patients with Solid Cancer

Germana A. Brito, Antonio P. Nassar, Benedito J. Pereira. *ACCamargo Cancer Center, Sao Paulo, Brazil.*

Background: Acute kidney injury (AKI) has emerged as an important toxicity among patients with advanced cancer treated with these drugs. The aim of this study was to describe the incidence, risk factors of AKI in patients receiving checkpoint inhibitors alone or in combination with another immunotherapy or chemotherapy.

Methods: We included all patients who received immune checkpoint inhibitors alone or combined with another immunotherapy or chemotherapy at AC Camargo Cancer Center from January 2015 to December 2019. AKI was defined as a increase 1.5 fold increase in creatinine from baseline within 12 months of checkpoint inhibitor initiation. We assessed the association between the baseline demographics, comorbidities, medications and risk of AKI using a competing risk model, considering death as a competing event.

Results: We included 614 patients in the analysis. The mean age was 58.4 ± 13.5 years, the mean baseline creatinine was 0.8 ± 0.18 mg/dL, and the baseline eGFR was 101.4 ± 33.2 ml/min. AKI occurred in 144 (23,5%) patients on average 14, 2 weeks after the beginning of treatment. The most frequent AKI etiologies were multifactorial (10,1%), hemodynamic (8,5%) and possibly related immunotherapy (3,6%). The likelihood of AKI was greater in the patients genitourinary cancer (sHR =2.84; 95% CI, 1.58-5.12, p < 0,01), with previous AKI history (sHR =2.1 95% CI, 1.34-3.42, p < 0,01) and taking anti-PD1/PD L1 combined with chemotherapy (sHR =1.73; 95% CI, 1.13–2.63, p < 0,01) (figure). An evaluation by a nephrologist occurred in 20,8% of the patients.

Conclusions: The patients receiving checkpoint inhibitors frequently developed AKI due to various etiologies. Genitourinary cancer, previous AKI and anti-PD1/PD-L1 combined with chemotherapy were associated with a higher likelihood of developing AKI.

Wunderlich Syndrome: Spontaneous Perinephric Hematoma in a Patient with Chronic Myelomonocytic Leukemia (CMML)

Nathaniel Klair, Sean Pickthorn, Salman B. Mahmood, Mark E. Rosenberg. *University of Minnesota Twin Cities School of Medicine, Minneapolis, MN.*

Introduction: Wunderlich syndrome describes the uncommon presentation of spontaneous perinephric hematoma that are most often caused by renal neoplasms. We present a case of bilateral spontaneous perinephric hematomas in a patient ultimately diagnosed with chronic myelomonocytic leukemia (CMML).

Case Description: A 62-year-old woman presented with acute onset right flank pain, hypotension, and anemia (Hgb 6.8 g/dL) requiring emergent transfusion. Workup showed WBC of 49x10^3/μL, platelets 380x10^3/μL, and Cr 0.9 mg/dL. CT revealed a large right perinephric hematoma, but no active extravasation was seen on angiography. The patient was stabilized with medical management and outpatient bone marrow biopsy was planned. Two days later she presented with acute onset left flank pain. CT showed a stable large right perinephric hematoma and a new left perinephric hematoma (Figure 1). Angiography revealed active extravasation from bilateral segmental renal arterial branches which were successfully embolized. Post embolization, the patient developed oliguric AKI (peak Cr 3.6 mg/dL), likely due to a combination of contrast exposure, ischemia from embolization and acute blood loss, and compression of the kidneys. She briefly required dialysis while her renal function recovered over a period of 2 weeks. During this time, a bone marrow biopsy was performed which revealed CMML. Treatment was initiated with hydroxyurea.

Discussion: The most frequent cause of spontaneous perinephric hematoma is primary renal malignancy or mass. CMML rarely has shown renal infiltration leading to renal failure but has no prior association with Wunderlich syndrome. While no biopsy was performed, we suspect this patient had leukemic infiltration of both kidneys which predisposed her to spontaneous bilateral perinephric hematomas in short succession.

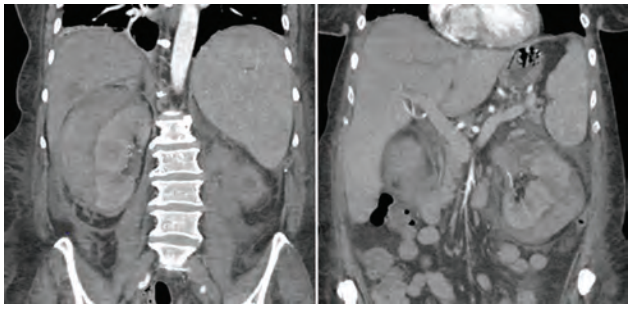

Figure 1: CT with contrast showing bilateral perinephric hematomas.

PUB329

Exploring Uncharted Territories: Unusual Distant Metastases in Renal Cell Carcinoma

Wern Lynn Ng,[1] Benjamin Ravichander,[1] Lillian Sangha,[1] Evelyn J. Calderon Martinez,[1] Lay She Ng,[2] Chandi Garg.[1] *[1]UPMC Harrisburg, Harrisburg, PA; [2]Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Metastatic renal cell carcinoma (RCC) is known for its tendency to disseminate to the skeletal system, particularly as lytic lesions. The predilection of this metastasis primarily involves vascular regions within the axial skeleton (e.g., vertebral bodies and the pelvis). While rare, there have been scant reports documenting the manubrium as the primary site of metastasis. In this context, we present a case of metastatic RCC, wherein the patient's initial manifestation manifested as chest pain.

Case Description: A 50-year-old male with 50 pack-years of smoking history, presented to the emergency department (ED) with right-sided chest pain aggravated by recent hand trauma. The patient reported progressive difficulty with overhead movements and right-hand lifting. He had no alleviating factors and denied shortness of breath, diaphoresis, or recent weight loss. Further evaluation ruled out acute coronary syndrome (ACS). The chest x-ray was unremarkable. However, a commuted tomography (CT) of the abdomen and pelvis raised concern about a large left-sided renal mass. He was discharged with outpatient follow-up. Within three weeks, the patient returned to ED due to worsening chest pain and now, a growing mass in the sternum. ACS was ruled out again. A chest CT scan revealed a concerning lytic lesion in the manubrium. To establish a diagnosis and stage of a presumed metastatic renal cell carcinoma, the patient underwent a positron emission tomography scan and bone biopsy of the lesion. The subsequent pathology report confirmed metastatic RCC. Treatment was initiated with immunotherapy (nivolumab and ipilimumab) and palliative radiation therapy targeting the sternum. Left radical nephrectomy and adrenalectomy with clean margins were performed. Ongoing treatment involves immunotherapy aimed at reducing the burden of metastatic disease.

Discussion: RCC commonly metastasizes to the lungs and lymph nodes, with axial skeletal involvement being less frequent. Sternal metastases are rare, likely due to the limited vascularity in this region compared to sites like the pelvis or vertebrae. However, RCC is a treatable cancer, and both surgical intervention and immunotherapy have shown efficacy in improving metastatic disease outcomes. Timely treatment can enhance quality of life and potentially even lead to metastatic disease regression.

PUB330

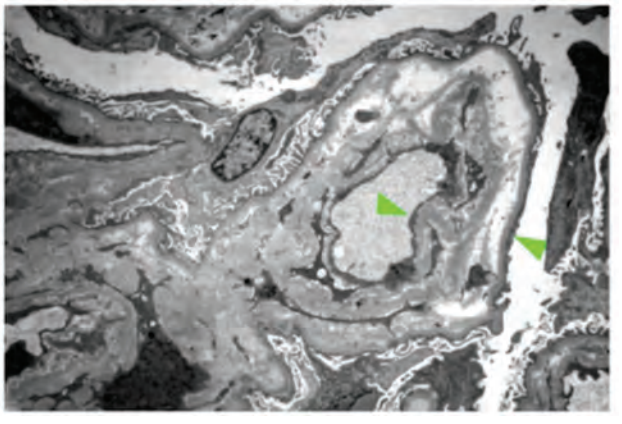
A Rare Case of Thrombotic Microangiopathy (TMA) with Lenvatinib

Chinnawat Arayangkool,[1,2] Thiratest Leesutipornchai,[1,2] Noppawit Aiumtrakul,[1,2] Manasawee Tanariyakul,[1,2] Titus David,[1,2] Chuong Dinh,[3] Lisa Kim.[3] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Hawaii Residency Programs Inc, Honolulu, HI; [3]The Queen's Health Systems, Honolulu, HI.*

Introduction: Lenvatinib is a rare cause of drug-induced TMA because its mechanism includes inhibition of VEGFR 1-3. The podocytes of the renal glomerulus produce VEGF, which is essential for the maintenance and proper function of adjacent endothelial cells. We report a patient on lenvatinib who developed TMA.

Case Description: A 65-year-old woman with recurrent endometrial carcinoma metastatic to the lung and liver, for which she received treatment with doxorubicin and bevacizumab. After completing eight cycles of this regimen, the patient developed whole-body swelling and was found to have uncontrolled hypertension and acute kidney injury with new-onset proteinuria attributed to the effects of bevacizumab. Consequently, the treatment regimen was discontinued and changed to pembrolizumab and lenvatinib. However, after ten days of this regimen, the patient presented with diarrhea. Her vital signs were significant for hypertension. A rise in creatinine level from 2.2 mg/dL to 5.2 mg/dL. Renal ultrasonography showed increased renal cortical echogenicity. Based on these findings, the patient underwent a kidney biopsy to confirm the diagnosis of an intrinsic renal cause. The finding of the left renal biopsy showed acute and chronic thrombotic microangiopathy with global glomerulosclerosis, moderate interstitial fibrosis, tubular atrophy with interstitial nephritis, and severe arteriosclerosis with evidence of fibroid necrosis. On electron microscopy, findings reveal microangiopathic changes consistent with the vascular endothelial growth factor inhibitors effect. As the left renal biopsy confirmed TMA as the cause of her AKI, Lenvatinib was discontinued. However, her renal function progressively declined, leading to ESRD requiring hemodialysis.

Discussion: Lenvatinib-associated TMA is a rare adverse effect. There is a case series of biopsy-proven TMA in patients on lenvatinib after prolonged exposure. However, our patient developed TMA shortly after lenvatinib exposure. TMA should be considered in patients on lenvatinib, and renal biopsy is recommended to confirm the diagnosis.



PUB331

A Rare Case of a Primary Renal Ewing Sarcoma

Robin Miller,[1,2] Elizabeth G. Ingulli.[1,2] *[1]Rady Children's Hospital San Diego, San Diego, CA; [2]University of California San Diego, La Jolla, CA.*

Introduction: Ewing's sarcoma is a neuro-ectodermal tumor that is classically found in long bones. A primary renal origin of an Ewing's sarcoma is very rare. It is estimated that there are less than 370 reported cases of a primary renal Ewing's sarcoma. This case presents a rare primary renal Ewing's sarcoma.

Case Description: A previously healthy 15 year old male presented with two months of hematuria and one day of left flank pain, as well as occasional migratory bone pain. Initial imaging with US kidneys and bladder revealed an area of calcification in the lower pole of the left kidney. Further imaging with CT abdomen and pelvis showed a left renal mass with associated calcification with extension into the renal pelvis. There were also lesions visualized in the liver, spine, and pelvis that were concerning for metastases. The patient was later found to have additional metastases in the skull and sternum. Initial differential diagnosis included Wilm's tumor, clear cell sarcoma, malignant rhabdoid tumor, and renal cell carcinoma. Diagnosis of Ewing sarcoma was made by biopsy of a lytic bone lesion and was confirmed on pathology of the left kidney following left nephroureterectomy. The patient is currently undergoing chemotherapy and responding well to treatment.

Discussion: This is a rare case of a primary renal Ewing's sarcoma. While more common primary renal tumors such as Wilm's tumor, clear cell sarcoma, and renal cell carcinoma may be higher on the differential in a patient presenting with a renal mass, it is important to keep less common tumors such as Ewing's sarcoma on the differential, especially in a patient presenting with bone pain and bony metastases. Although a primary renal Ewing's sarcoma is very rare, this patient's presentation was consistent with other cases of primary renal Ewing's sarcoma. In a metanalysis of cases of primary renal sarcoma that included 48 patients, Hakky et al found that 36 (73%) presented with flank pain and 15 (31%) presented with hematuria. This is an aggressive tumor so rapid diagnosis and treatment are key to optimizing outcomes.

PUB332

A Case of Thrombotic Microangiopathy (TMA) Secondary to Bevacizumab Followed by Acute Interstitial Nephritis (AIN) Secondary to Nivolumab: A Strong Case for Serial Biopsies

Omar Osman, Roman A. Shingarev, Kristen Tomaszewski, Hanny Sawaf. *Cleveland Clinic, Cleveland, OH.*

Introduction: In recent years, onconephrology has gained prominence as a crucial field at the intersection of oncology and nephrology. With the rapid growth of cancer treatments that are often used concurrently, it has become important for oncologists and nephrologists alike to recognize unique patterns of drug-related kidney injury and develop a consistent and efficient approach to establishing etiology of acute kidney injury (AKI). Here we present a patient who experienced biopsy proven thrombotic microangiopathy (TMA) caused by bevacizumab, was switched to nivolumab which resulted in biopsy proven acute interstitial nephritis (AIN).

Case Description: Patient is a 69-year-old female with a medical history of stage IV malignant mesothelioma of the lung. This was treated with platinum-based therapy, pemetrexed and bevacizumab followed by maintenance therapy with bevacizumab. Patient initially had normal kidney function with a baseline creatinine of 0.9mg/dL, however, 2 years after initiation of therapy her kidney function worsened, with a creatinine rising to 2.4mg/dL and a urine protein to creatinine of 2.7g/g. Patient underwent a kidney biopsy revealing focal segmental and global glomerulosclerosis with microangiopathic features as well as moderate arteriosclerosis. A diagnosis of bevacizumab induced TMA was made and this medication was stopped. Patient then began treatment with the immune checkpoint inhibitor (CPI) nivolumab. Five months after her first kidney biopsy and 3 months after beginning treatment with nivolumab, patient's creatinine rose again to then new peak of 7 mg/dL. Repeat kidney biopsy was obtained revealing acute tubulointerstitial nephritis which was suspected to be secondary to nivolumab. This medication was held, patient was started on a short prednisone course with recovery to baseline kidney function followed by a taper and plan to possibly rechallenge with an CPI.

Discussion: As demonstrated by this case, serial kidney biopsies may be required to ascertain etiologies of recurrent AKI in patients exposed to different cancer treatments. These biopsies can effectively guide oncological treatment and help avoid progression to end-stage kidney disease that would otherwise severely limit further treatment options and preclude patients' participation in new drug trials.

PUB333

Kidney Palliative Care: Key Tool to Facilitate Shared Decision Making

Kaitlyn Lersch, Pooja D. Amarapurkar, Jane O. Schell. *UPMC, Pittsburgh, PA.*

Introduction: Patients with cancer and kidney disease have complex symptoms and needs. This is especially true for those with advanced chronic kidney disease (CKD) who are at risk for worsening progression due to cancer-directed therapies or their side effects. Palliative care is team-based care that focuses on managing symptoms and addressing goals of care including kidney treatment decisions. Our institution developed a specialty kidney palliative care (KPC) team to manage these complex patients through collaboration with referring clinicians. The following case describes how KPC can promote patient-centered care in a patient with advanced CKD and cancer.

Case Description: An 80-year-old man with CKD stage 3bA2 established care with our KPC team. His kidney function remained stable until about a year before his cancer diagnosis, with estimated GFR dropping to the mid-20s. These notable changes prompted a goals of care discussion that led to a decision for medical management without dialysis. He was later diagnosed with metastatic lung cancer. After receiving this diagnosis, the KPC team worked with both the patient and his wife to outline goals of palliative chemotherapy, which included a quality of life with the ability to garden, enjoy reading and be at home with family. Shortly after starting treatment, he required hospitalization for dehydration and AKI in the setting of diarrhea related to the chemotherapy. Due to the strong relationship established with the patient and his family, the KPC team collaborated with his oncology team to help determine that starting dialysis and continuing chemotherapy were not consistent with his goals. These relationships and prior discussions helped the patient choose hospice care, passing away peacefully at home.

Discussion: This case exemplifies how patients with advanced kidney disease and cancer benefit from specialty palliative care. It demonstrates how the KPC team has a role in having early conversations regarding goals, revisiting these goals, and then collaborating with oncology. It allows patients and their families to build trust in their medical team, which is especially needed during challenging decisions. It gives patients and families the opportunity to express their values and receive patient-centered care especially at end of life.

PUB334

Proliferative Glomerulonephritis with Monoclonal IgG Deposits: Yet Another Unusual Presentation

Pranjal Sharma,[1,2] Rajat Maheshwari,[3] Harpreet S. Grewal,[4,2] Leal C. Herlitz,[5] Carmen J. Julius,[6] Gagandeep Dhillon,[7,2] Ripudaman S. Munjal,[8] Rahul Kashyap.[9,2] *[1]Northeast Ohio Medical University, Rootstown, OH; [2]Global Remote Research Scholars Program, St Paul, MN; [3]Premier Renal Care LLC, Cuyahoga Falls, OH; [4]Radiology Associates of Florida, Pensacola, FL; [5]Cleveland Clinic, Cleveland, OH; [6]Akron Children's Hospital, Akron, OH; [7]University of Maryland Baltimore Washington Medical Center, Glen Burnie, MD; [8]San Joaquin Kidney Clinic, Stockton, CA; [9]WellSpan Health, York, PA.*

Introduction: Proliferative Glomerulonephritis with Monoclonal IgG Deposits (PGNMID) is a relatively rare diagnosis with variable presentation. When detectable, the disease is typically indolent rather than malignant. Here we report a case of PGMNID which presented clinically as Rapidly Progressive Glomerulonephritis (RPGN).

Case Description: A 62-year-old man presented to his primary care physician's office with complaint of diarrhea for one day and was admitted for acute kidney injury. Urine sediment was active, and the patient had nephrotic range proteinuria. Serologic workup including Antineutrophil cytoplasmic antibody, double strand-DNA antibody, free light chains, electrophoresis and imunofixation, and bone marrow biopsy were negative for any monoclonality. Kidney biopsy showed diffuse proliferative and crescentic glomerulonephritis with IgG3–kappa restricted deposits, consistent with PGNMID. The patient required dialysis initiation and corticosteroids were administered. The patient declined additional immunomodulatory treatment. The patient remains hemodialysis dependent.

Discussion: In summary, we present a case of PGNMID presenting clinically as RPGN without evidence of hematologic malignancy. IgG subclass staining should be performed in such cases without a peripherally detected clone. This case highlights the potential for severe renal damage from monoclonal proteins despite an indolent or even undetectable hematologic clone. The diagnosis needs further studies to better understand the entity and develop a standard treatment regimen for it.

PUB335

A Rare Manifestation of Multiple Myeloma in a Patient with Kidney Injury

Nader Ismail, Goutham Kondapi, Anthony Chang, Marco A. Bonilla Arevalo. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Introduction: Acute kidney injury (AKI) is a common complication of multiple myeloma (MM), most frequently attributed to underlying myeloma cast nephropathy. By contrast, infiltration of kidney tissue by neoplastic plasma cells is a rare occurrence and a rare mechanism of acute kidney injury in these patients.

Case Description: A 75-year-old male with a past medical history of long-standing hypertension and diabetes was admitted for evaluation of AKI. He reported unexplained weight loss but was otherwise asymptomatic. Upon laboratory evaluation, he was found to have increased serum creatinine from his baseline of 1.0 mg/dL to 3.8 mg/dL, a urinalysis remarkable for proteinuria, and a urine protein and creatinine ratio of 8.3 g/g. Further evaluation revealed free kappa and lambda light chains of 1.0/432 mg/dl with a ratio of 0.0025. Serum protein electrophoresis showed a monoclonal free lambda. Serological work up was negative. Renal ultrasound was unremarkable. A kidney biopsy demonstrated a Lambda light chain-restricted plasma cell infiltration and a Light chain proximal tubulopathy, non-crystalline type (lambda light chain-restricted). Subsequently, he underwent a bone marrow biopsy showing a lambda-restricted plasma cell myeloma with 50% plasma cells and started on daratumumab-based therapy.

Discussion: The etiology of kidney disease in patients with multiple myeloma can be multifactorial. On kidney biopsy, a broad spectrum of kidney lesions has been described. This case demonstrated a rare mechanism of acute kidney injury in a patient with MM and highlights the importance of kidney biopsy in the diagnosis and prognosis of these patients.

PUB336

Renal Involvement in Chronic Lymphocytic Leukemia: A Case Report

Vaishnavi Singh, Peter Van. *Willis-Knighton Health System, Shreveport, LA.*

Introduction: Chronic Lymphocytic Leukemia (CLL) is a primary bone marrow malignancy characterized by the clonal expansion of mature B lymphocytes. Although CLL primarily affects the bone marrow and peripheral blood, extra-medullary involvement can occur, including renal manifestations. Kidney disease in CLL patients can have significant implications on prognosis.

Case Description: We present a case of a 51-year-old female with a 12-year history of CLL who presented with weakness, hematuria, proteinuria, and elevated creatinine. Initially, she was suspected to have acute tubular injury secondary to the usage of nonsteroidal anti-inflammatory drugs. Over time, her renal function progressively declined, necessitating the initiation of dialysis. A kidney biopsy revealed renal involvement of CLL, showing leukemic infiltration along with findings suggestive of membranoproliferative glomerulonephritis and the possibility of cryoglobulinemic glomerulonephritis. However, due to limited sample, additional immunofluorescence studies could not be performed. Treatment with Rituximab, an anti-CD20 monoclonal antibody, was initiated. The patient was also started on ibrutinib, a Bruton's tyrosine kinase inhibitor, and is currently being managed with it.

Discussion: Renal involvement in CLL is a complex process that can occur through various mechanisms, including leukemic infiltration, glomerular diseases, extrarenal obstruction, tumor lysis syndrome, electrolyte disorders, and medication side effects. In our case, the kidney biopsy demonstrated interstitial infiltrates of small CD20+/CD5+ B cell lymphocytes, indicating direct leukemic infiltration. Additionally, the presence of membranoproliferative glomerulonephritis raised the possibility of cryoglobulinemic glomerulonephritis. This case report underscores the importance of recognizing and managing kidney involvement in CLL patients. Understanding the multifaceted mechanisms of renal disease in CLL can facilitate early diagnosis and appropriate treatment selection, potentially improving patient outcomes. Further research is warranted to enhance our understanding of CLL-related kidney disease and refine treatment strategies.

PUB337

AKI, Glomerulonephritis, and Tubulointerstitial Nephritis Following Prescription of Anticancer Drugs: VigiBase Analysis

Soo-Young Yoon,[1] Dae Kyu Kim,[1] Hyo Jin Lee,[1] Yang Gyun Kim,[2] Ju young Moon,[2] Hyeon Seok Hwang,[1] Kyunghwan Jeong,[1] Jin sug Kim.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Anticancer drugs can have varying effects on the kidneys, depending on their characteristics. Some drugs may be nephrotoxic and can potentially cause renal impairment. This is due to the damage, which can range from mild to severe, inflicted on renal tissues during drug processing and elimination. We aimed to to analyze the risk of renal adverse reactions from several types of anticancer drugs using a global reporting system.

Methods: We conducted an analysis on VigiBase, the World Health Organization pharmacovigilance database, consisting of 120,715,116 reports from Dec 1967 to Jul 2022 via disproportionate Bayesian reporting method. Information component (IC) compares observed and expected values to find the associations of 259 anticancer drugs with acute kidney injury (AKI), 101 anticancer drugs with glomerulonephritis (GN), and 91 anticancer drugs with tubulointerstitial nephritis (TIN). We further categorized the anticancer drugs into five groups: cytotoxic therapy, hormone therapy, immunotherapy, targeted therapy, and miscellaneous group.

Results: We observed 22,426 AKI, 1,312 GN, and 1,084 TIN reports which were reported as anticancer drug-related renal adverse reactions. Analyzing IC_{025} of each anticancer drugs separately, AKI cases following 85 of 259 anticancer drugs significantly increased. GN case reports after administering 16 of 101 anticancer drugs were statistically significant. We observed significantly higher TIN events in 17 of 91 anticancer drugs which we assessed. Notably, immunotherapy and targeted therapy anticancer drugs were frequently associated with renal injuries, while no significant renal adverse reactions were observed in the hormone therapy group across all AKI, GN, and TIN categories.

Conclusions: AKI, GN and TIN were substantially observed following the administration of anticancer drugs. Noticeably, renal adverse reactions following immunotherapy and targeted therapy, which have been experiencing an increase in utilization, were more prominent when compared to hormone therapy. Clinicians should consider the increased risk of renal adverse reactions after specific anticancer drugs.

PUB338

Anti-Complement Factor H Autoantibodies of the IgM Class and Atypical Hemolytic Uremic Syndrome (aHUS)

Gianluigi Ardissino, Thomas Ria, Maria Cristina Mancuso, Luigi Porcaro, Valeria Amico, Massimo Cugno. *Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Introduction: We have recently reported anti-complement factor H autoantibodies of the IgM class as a rare cause of atypical hemolytic uremic syndrome (aHUS).

Case Description: Herein, we describe the case of a 53 yo woman diagnosed with gastric MALT (mucosal-associated-lymphoid tissue) lymphoma at the age of 39yo treated with Rituximab and Bendamustine achieving minimal residual disease. Following diagnosis of the laboratory work-up for complement abnormalities excluded regulatory gene mutations whereas it revealed a very high level anti-CFH autoantibodies of the IgM class (with undetectable anti-FH IgG and IgA). Auto-antibody title was repeatedly confirmed high ranging from 34 and 66 AU/mL (normal value < 10.3 AU/mL) over an observation period of 6 months. C3 levels were also low, ranging from 58 and 62 mg/dL (normal values 90-180 mg/dL) with normal C4. Soluble C5b9 was very high during the acute phase (1881 ng/mL (normal values 139-463 ng/mL) and progressively decreased on eculizumab treatment reaching the normal level of 331 ng/mL. The patient is presently continuing C5-inhibition and aHUS remains into remission.

Discussion: This case-report underlines that auto-antibodies to CFH are not only of the IgG class but also of of the IgM class thus the latter should be part of the diagnostic workup of any case of aHUS.

PUB339

Vitamin B12 Deficiency: Equivocal or Pernicious?

Kylee M. Koehler,[1] Christopher H. Girgis.[2] *[1]Burrell College of Osteopathic Medicine, Las Cruces, NM; [2]Brevard Nephrology Group, Merritt Island, FL.*

Introduction: Screening for vitamin B12 is not recommended in healthy individuals. Deficiency can include a wide range of symptoms. The iconic finding of B12 deficiency is macrocytic, megaloblastic anemia, and increased methylmalonic acid. Several reported cases of B12 deficiency have been mistaken for MAHA, thrombocytopenia, and in this review, TTP. Characteristics of TTP include fever, microangiopathic hemolytic anemia, thrombocytopenia, renal injury, and/or neurological symptoms. We present the case of a 63-year-old male with B12 deficiency originally misdiagnosed with TTP.

Case Description: This is a 63-year-old male with PMH significant for stroke who presented to the ED at an outside facility due to a fall in his garage. He experienced agitation, multiple skin lesions on the arms consistent with bruising, and reports of suicidal ideation. For severe anemia, patient was transfused. Hematology/oncology suggested catheter placement for plasmapheresis. The patient was transferred to our facility where nephrology was consulted to evaluate thrombocytopenia with possible TTP and begin plasmapheresis. Given suicidal ideations, psychiatry involuntarily committed the patient upon arrival. Nephrology believed this to be B12 deficiency with pancytopenia, not TTP due to elevated MCV. B12 was 276. Nephrology was concerned for pernicious anemia and recommended against plasma exchange. The patient regardless refused plasmapheresis. He did agree to 1000 mcg IM of cyanocobalamin, administered every 24 hours over 3 days. MRI confirmed absence of subacute combined degeneration. Labs improved substantially after treatment. Full workup was performed for B12 deficiency. He continued to have agitation but was deemed competent and the involuntary commitment was lifted with the patient discharged.

Discussion: Vitamin B12 is considered deficient with levels measuring less than 200 ng/L, with borderline deficiency of 200-400 ng/L considered equivocal, with recommendations to follow up with MMA levels to determine if this is true deficiency. MMA levels are highly sensitive and specific for identifying vitamin B12 deficiency. Psychiatric symptoms of B12 deficiency may be permanent, especially with prolonged time to treatment. In this case, the high MCV and pancytopenia lead to the suspicion of pernicious anemia, which was confirmed with elevated MMA and homocysteine, positive parietal cell and intrinsic factor antibodies.

PUB340

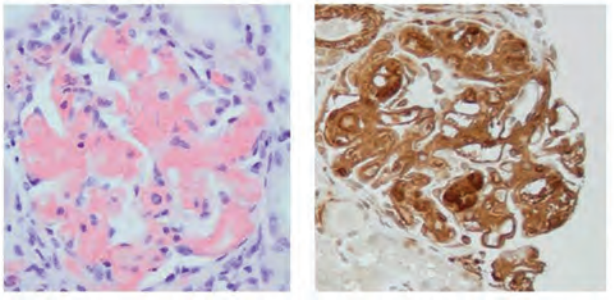
Renal Amyloid A (AA) Amyloidosis in a 24-Year-Old Drug User

Laura Biederman,[1,2] Anjali A. Satoskar,[1] Alana Dasgupta,[1] Sergey V. Brodsky.[1]
[1]The Ohio State University, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.

Introduction: Amyloidosis is an infiltrative disease caused by misfolded proteins depositing in tissues. There are currently described 14 types of amyloid that can involve the kidney. Herein we report a case of AA amyloidosis occurring in a 24-year-old male with a history of intravenous drug abuse.

Case Description: The patient is a 24-year-old male with a past medical history of intravenous drug abuse for 3 years and no other significant clinical or family history. He presented with bilateral edema and bilateral pleural effusions. Serum creatinine was 1.67 mg/dL (baseline 1mg/dL). Urinalysis showed 3+ protein and 1+ blood, serum albumin was 0.9 g/dL. In a kideny biopsy, the glomeruli showed diffuse infiltration of the mesangium by Congo red-positive amyloid. Immunofluorescence did not show dominance for either kappa or lambda light chain or other heavy chains. Electron microscopy showed randomly arranged fibrils with an average diameter of 10.4 nm. IHC for amyloid A was positive; a transthyretin/prealbumin was negative. Liquid chromatography-tandem mass spectroscopy (LC-MS) confirmed the presence of AA amyloid.

Discussion: Herein we describe a 24-year old patient, which, to the best of our knowledge, is the youngest described in the literature with AA amyloidosis associated with drug abuse. The patient had no history of inflammatory disorders, and no family history of amyloidosis or renal disease. Therefore, amyloid was attributed to the drug abuse. AA amyloid can be misdiagnosed as AL amyloid, and immunohistochemistry can be unreliable, so confirmatory testing by LC-MS should be performed if there is any discrepancy. For AA amyloidosis treatment focuses on controlling the underlying inflammatory process with the goal of reducing the amount of circulating SSA protein by reducing is production in the liver. Unfortunately, this patient was lost to follow up.



Congo Red positivge material in the glomerulus that stains positively by IHC with an antibody to Amyloid A.

Proteasome Components in the Low-Centrifugation Pellet of Urinary Extracellular Vesicles

Dana Bielopolski,[1,3] Luca Musante,[4] Douglas Barrows,[1] Henrik Molina,[1] Jonathan N. Tobin,[5,1] Rhonda Kost,[1] Uta Erdbruegger.[2] *[1]The Rockefeller University, New York, NY; [2]University of Virginia, Charlottesville, VA; [3]Rabin Medical Center, Petah Tikva, Israel; [4]University of Pennsylvania, Philadelphia, PA; [5]Clinical Directors Network Inc, New York, NY.*

Background: High-speed ultracentrifugation is a commonly employed technique for isolating small extracellular vesicles (EVs). In contrast, the low-speed centrifugation pellet can be an advantageous source for large EVs. In this study we sought to describe and compare the characteristics of EV pellets obtained through different centrifugation velocities, with a specific focus on their protein content and cellular localization.

Methods: A healthy volunteer provided a morning urine sample that was divided into three aliquots. Each urine aliquot underwent centrifugation to eliminate cell debris, and the resulting supernatant was then subjected to a centrifugation at 21,200g to generate a pellet known as P20. The supernatant from P20 was subsequently centrifuged at 164,000g, resulting in a pellet referred to as P100. The P20 pellets were subjected to uromodulin depletion using a low ionic strength buffer, while the P100 pellets were purified using size exclusion chromatography. The individual pellets were analyzed using mass spectrometry separately and combined.

Results: in all three replicates 929 proteins were identified the P20 pellets, 1103 proteins in the P100 pellets, and 1676 proteins in the combined P20 and P100 pellets. 398 proteins were uniquely identified in P100 and 224 were uniquely identified in P20. 473 proteins were uniquely expressed in the combined P20+ P100 that were not identified in either fraction alone. The abundance of S19 proteasome subunit components were increased in P20 compared to P100.

Conclusions: Implementing low centrifugation along with a high ionic strength buffer effectively prevents co-sedimentation and increases detection yield. The uEVs P20 pellet contained proteasome components, specifically the 19S subunit indicating a shared pathway potentially associated with apoptosis.

Renal Interstitial Fibrosis Association with Hypertension (HTN), Diabetes Mellitus (DM), Ultrasound Measured Sinus Fat, and Parenchymal Thickness

Jafar Alsaid, Ana I. Stark, Mu'ath N. Abdeen. *Ochsner Medical Center, New Orleans, LA.*

Background: Interstitial fibrosis is an important component of a kidney biopsy to determine chronic renal disease. In this study we wanted to determine the correlation between biopsy proven interstitial fibrosis, HTN, DM, ultrasound measured sinus fat as well as parenchymal thickness.

Methods: Retrospective cross-sectional study included all kidney biopsies performed by the interventional Nephrology division in the Nephrology department at Ochsner medical center over 2 years from 2021- 2023. Demographic factors, HTN and DM were registered. Renal function was calculated using CKD MB. The extent of interstitial fibrosis was obtained from kidney biopsy results. The sinus fat length was measured from longitudinal sagittal US image. The total renal length was measured on the same image. The renal parenchymal thickness was measured by subtracting the longitudinal sagittal length of the sinus fat from the total kidney length. The percentage of sinus fat length was measured by dividing the length of sinus fat over the total renal length for the ipsilateral side of the biopsy. SPSS 25 was used statistics analysis.

Results: Total biopsies were 60. Mean age: 50 years. (SD 17.5, SE 2.27). Male gender was 45%. Mean BMI 29.3 kg/m2 (SD 7.2, SE 0.9) 23 % had DM, 55 % had HTN and 23% had both. Mean Interstitial fibrosis 20%. which was significantly more among patinets with HTN and DM (33%) as compaired to patients with only HTN (23%) or thouse without HTN or DM (12%). Mean S. Cr. 2.3 mg/dl (SD 2.2, SE 0.28) Mean eGFR: 42ml/min. (SD 19.3, SE 2.5)

Conclusions: Interstitial fibrosis was significantly associated with age, gender, HTN, DM, S. creatinine and eGFR but not sinus fat length or parenchymal thickness. Patients with HTN and DM had more interstitial fibrosis compared patients with HTN alone, and patients without HTN or DM.

Independent Variables	Correlation Coefficient	p Value
Age	0.36	0.005

Statin Therapy Activates a Programme of Skeletal Muscle Wasting In Vitro

Emma L. Watson, James Burton. *University of Leicester, Leicester, United Kingdom.*

Background: Skeletal muscle wasting is a serious and common complication of chronic kidney disease (CKD) which starts very early in the disease process. This is an important clinical problem as it is strongly associated with increased risk of mortality and decreased quality of life. Despite its prevalence and impact, mechanisms of skeletal muscle (SM) wasting are unclear. One possible contributor is statin medication that CKD patients are frequently prescribed, which are documented to have negative effects upon muscle health. The aim of this study was to assess the effect of simvastatin therapy on protein degradation in human derived primary skeletal muscle cells (HDMC's).

Methods: Isolated HDMCs were cultured for 4 days in medium supplemented with foetal bovine serum (FBS, 20%), followed by 7 days in either 2% horse serum (HS) to establish mature myotubes. HDMC's (n = 5 CKD patients) were incubated with either 10μM and 30μM simvastatin for 24h and effects upon atrophy were assessed by myotube diameter by immunofluorescence, and activation of protein degradation and inflammation pathways by PCR.

Results: Cells exposed to10μM and 30μM simvastatin displayed significant reductions in myotube diameter (Control = 9.904μm ± 2.56, 10μM = 8.424μm ± 1.68 and 30μM = 7.998μm ± 2.05, p=0.0036. 10μm statin therapy significantly increased the mRNA expression of RRIM63 (a muscle specific E3 ligase; 3.7-fold increase, p=0.005) and resulted in significant intramuscular inflammation (IL6 = 1.6- fold increase, p=0.008 and TNFα = 2.7-fold increase, p<0.001). Similar effects were seen with 30μm statin therapy which resulted in significant inflammation (IL6 = 1.7-fold increase, p=0.001, TNFα = 2.2-fold higher, p=0.025 and CCL2 = 2.2-fold increase, p=0.027).

Conclusions: Short term exposure of HDMS's to 10μM and 30μM simvastatin resulted in myotube atrophy, likely to be regulated by an increase in intramuscular inflammation. Whilst statin therapy has strongly beneficial effects for these patients in terms of reducing cardiovascular risk, an unwanted side effect is muscle wasting. It is unknown if this is an effect that is restricted to simvastatin alone, or also occurs with other statin use. This early pilot data suggests that we might need to think about strategies to preserve muscle mass in patients that are prescribed this class of drugs.

PUB344

Comparison of Two Scores for Renal ANCA-Associated Vasculitis (AAV) in Predicting Renal Outcomes

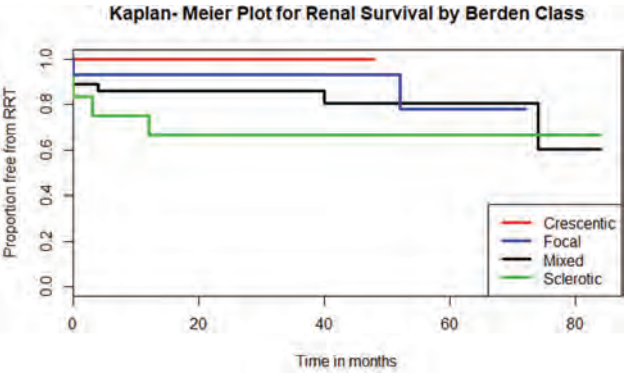
Nathan Lorde,[1,2] Mysore K. Phanish,[1] Fiona E. Harris,[1] David Makanjuola,[1] Rukma Doshi,[1] Nicholas Cole,[1] Bhrigu Raj Sood.[1] *[1]Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom; [2]The Dudley Group NHS Foundation Trust, Dudley, United Kingdom.*

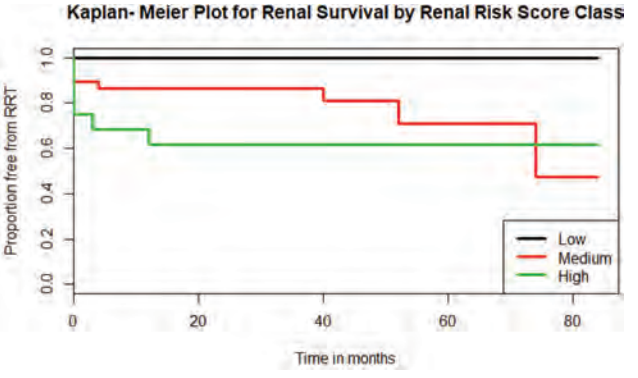
Background: ANCA associated vasculitis (AAV) is a rare but important cause of renal impairment and ESRD. Two classifications used for prognostication of renal AAV at presentation are Berden et al (Histopathologic classification of ANCA-associated glomerulonephritis. J Am Soc Nephrol.2010.21(10)) and the renal risk score -Brix et al (Development and validation of a renal risk score in ANCA-associated glomerulonephritis. Kidney Int.2018.94(6)). We aimed to test the 2 scores in our regional vasculitis centre's renal AAV cohort.

Methods: Review of records and renal biopsy of patients who presented from January 2012 to December 2016.

Results: 83 patients were included. 14 developed ESRD. 8 required early RRT but recovered and are not counted as ESRD. Berden Class We found no statistically significant relation between Berden class and ESRD and it did not predict recovery from early need for RRT. As KM curves cross at 52 months- fig 1-we calculated Cox proportional hazard up to 48 months. There was no statistically significant hazard There was significant association with creatinine at 1 year but not 4 Renal Risk Score Again the KM plot-fig 2-overlap. Cox hazard analysis up to 48 months found a hazard ratio of 4.178 for risk score class (p= 0.0017). The classification of our cohort using the renal risk score statistically significantly associated with ESRD but did not predict recovery from RRT. Also the renal risk class significantly associated with creatinine at 1 and 4 years.

Conclusions: In our cohort renal risk score by Brix et al performed better as predictor of ESRD and future creatinine than Berden class.





PUB345

The Role of Mitochondrial Metabolism in Inflammation Process of Brain-Dead (BD) Patients

Jordi Vilardell,[1,2] Irene Silva,[1] Beatriz Bardaji de Quixano,[1] Montserrat M. Diaz Encarnacion.[1,2] *[1]Fundacio Puigvert, Barcelona, Spain; [2]Universitat Autonoma de Barcelona, Barcelona, Spain.*

Background: As previously established, the renal prognosis of the recipient depends on the donor type. The decline in renal function has been observed to be greater in deceased donors (DD). We analyzed a cohort of brain-dead patients (DD). This could be related to the pre-implantation inflammation state and the development of fibrotic processes. Succinate, an intermediate in mitochondrial metabolism, plays a key role in the inflammatory processes of different pathologies. On the other hand, we observed previously, the involvement of adenosine pathway (linked to mitochondrial ATP production) in the same process. The aim of this study was to determine whether DD samples, succinate and purinergic pathways are involved in the infiltration of inflammatory cells.

Methods: Serum and whole cell extracts from circulating monocytes of 27 Brain Dead (BD) and 10 healthy volunteers (HV) were incubated in a Custom Quantibody array to determine the levels of 18 monocyte/macrophage markers (CCL2/MCP-1, CCL3/MIP-1a, CD163, B7-1/CD80, B7-2/CD86, ICAM-1, IFN-γ, IL-10, IL-13, IL-1b, IL-4, IL-4 Rα, IL-6, RANTES, TACE, TGF-β1, TNF-α and VEGF). Succinate levels were measured in serum from the same samples with the EnzyChromTM Succinate Assay Kit. All statistical data was analyzed using GraphPad Prism 5.

Results: The results showed that in BD serum compared to HV ones, there was a significant increase in the expression of cytokines involved in monocyte recruitment and adhesion. Serum levels of IL-6, implicated in polarization of macrophages towards the proinflammatory subtype, were higher in BD. Concerning monocyte protein extracts, a significant increase in anti-inflammatory M2 proteins, such as CD163, IL-4Ra and IL-13 was observed. BD succinate levels in sera were increased in the same way.

Conclusions: Taken together, these results would indicate that in BD samples, there would be recruitment and differentiation of monocytes to macrophages towards the M1 or M2 subtype. Most of the molecules found to be upregulated belong to proteins related to the M2 phenotype, leading us to suggest that in BD, the process is mainly reparative/pro-fibrotic.

PUB346

Improving Transition of Care in Pediatric Patients with CKD via a Remote Education Program

Melvin Chan, Sarah E. Young, Melisha G. Hanna. *University of Colorado, Denver, CO.*

Background: Healthcare transition is the process of preparing a pediatric patient for the adult care model. There are no studies evaluating methods for improving transition readiness in patients with chronic kidney disease (CKD). Our project evaluates the effectiveness of an education program.

Methods: Eligible patients between 14-22 years of age with CKD stage 2 or higher were approached about this quality improvement project at a single pediatric center covering a 7 state referral region. Transition readiness was assessed by electronically administering the Transition Readiness Assessment Questionnaire (TRAQ), a validated tool evaluating 4 key domains of readiness. All patients received written and verbal education to address deficit domains. Coaching sessions were also offered, reinforcing written information and occurring every 3 months via telephone. After 6 months, a follow-up TRAQ was administered. Paired t-test was employed to compare pre- to post-education scores, and repeated measures ANOVA was used to evaluate the effects of coaching sessions.

Results: Thirty-four patients enrolled in the program, with 15 patients being eligible for the 6-month follow-up TRAQ survey. Ten patients (67%) completed the follow-up survey, and 5 of them requested for coaching sessions. Both cohorts showed significant improvements in multiple domains (Figure 1). Coaching and education sessions did not show more significant improvement than education alone in transition readiness.

Conclusions: Our preliminary data suggest that education and coaching sessions may be an effective, feasible method for improving transition readiness from pediatric to adult CKD care. Additional research is needed to assess this intervention in a larger cohort and to see if this intervention will translate to improved clinical outcomes.

PUB347

Efficacy and Safety of Eculizumab in Enteroaggregative E. coli-Associated Partial Hemolytic Uremic Syndrome

Kiran K. Upadhyay, Ratna Acharya. *University of Florida, Gainesville, FL.*

Introduction: Partial hemolytic uremic syndrome (HUS) presents atypically without the full triad of classical HUS. We report the utility of eculizumab in enteroaggregative *E.coli* (EAEC) associated partial HUS.

Case Description: A 2-year-old previously healthy female presented with vomiting. Evaluation showed an afebrile normotensive child with non-immune hemolytic anemia, oliguric acute kidney injury (AKI) but without thrombocytopenia and peripheral schistocytes. Bloody stools appeared later; stool examination for Shiga toxin (ST) was negative but positive for EAEC. Bone marrow examination showed no malignancy. Serum complements were normal but soluble complement 5b-9 was elevated. She required several sessions of hemodialysis (HD) and received one dosage of eculizumab with rapid reversal of AKI and hemolytic markers (Fig 1). Kidney biopsy revealed acute tubular injury (ATI) and segmental glomerular basement membrane splitting, with no glomerular or vascular thrombosis (Fig 2). No further dosages of eculizumab were required. Genetic testing was negative for complement mutations or deficiencies. A follow-up 4 weeks later showed persistent normalization of renal function and hematological markers, without any adverse effects.

Discussion: Efficacy of eculizumab in atypical HUS and in severe ST associated HUS has been described. We report its efficacy in EAEC associated partial HUS as well. Typical histologic manifestations of HUS may not be present in partial HUS as shown here. In one study of HUS patients, ATI was present in 70% and GBM duplication was present in 76% of those without peripheral schistocytes. This is an interesting novel finding which will need to be studied further.

PUB348

Assessment of Tryptophan Metabolism in Pediatric ESKD

Brandon M. Fairless,[1,2] Joseph Alge.[1,2] *[1]Baylor College of Medicine Department of Pediatrics, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: End-stage kidney disease (ESKD) is associated with dysregulated tryptophan metabolism leads to systemic accumulation of toxic tryptophan metabolites derived from the indole and kynurenine pathways, which have been linked to systemic inflammation and an increased risk of thrombotic events and cardiovascular disease. Our study aimed to identify clinical variables that impact the plasma concentration of toxic tryptophan metabolites in children with ESKD on chronic hemodialysis (HD) and peritoneal dialysis (PD).

Methods: We designed a single-center cross-sectional study of children on chronic dialysis. Patients who received a kidney transplant between enrollment and sample collection were excluded. A total of 18 subjects had samples collected (HD n = 10; PD n = 8). Clinical characteristics are shown in Table 1. Serum specimens were collected at the time of routine monthly labs and were analyzed by liquid chromatography tandem mass spectrometry to measure tryptophan metabolites of the serotonin, indole, and kynurenine pathways. The association of target metabolites with demographic and clinical variables was determined t-test and Pearson correlation coefficients.

Results: Patients with residual renal function had a lower kynurenine: tryptophan (kyn:tryp) ratio (0.213 +/- 0.0553 vs 0.291 +/- 0.0564: t = - 2.885: p = 0.011). Serum serotonin level was positively correlated with the normalized protein catabolic rate (nPCR) ($r = 0.568$, $p = 0.0175$). However, there were no differences based on demographic variables, dialysis modality, or dialysis vintage.

Conclusions: Dialysis modality does not appear to influence tryptophan metabolism in children with ESKD. However, residual renal function is associated with a lower kyn:tryp ratio, which could reflect a reduction in systemic inflammation and immune dysregulation. The correlation between serum serotonin levels and nPCR suggests that nutrition status could influence serotonin-mediated pathways involved in neurocognitive outcomes. Larger prospective studies are needed to further evaluate the association of dysregulated tryptophan metabolism and clinical outcomes associated with pediatric kidney disease.

Audio/Podcasts and Art: A Collaboration Between the Renal Patient Support Group (RPSG) and the Kidney Disease and Renal Support Group (KDARs) for Kids and ZtormLabostix Productions

Shahid N. Muhammad. The Renal Patient Support Group (RPSG); The Kidney Disease and Renal Support Group (KDARs) for Kids; ZtormLabostix Productions. *Coventry University, Coventry, United Kingdom.*

Background: Chronic Kidney Disease (CKD) is 'recognized' as a silent, irreversible long-term condition (LTC), and tends to establish itself as a health complication and/ or co-morbidity. Service user access to educational support surrounding kidney care can be challenging between health sectors owing to clinical environments. **Aims:** To understand how Audio/ Podcasts and Art offer a collaborative basis for Service Users and Service Providers to align healthcare practices. **Objectives:** The Audio/ Podcasts and Art have

been focused between two leading educational social media platforms to help highlight pertinent aspects surrounding healthcare and disease.

Methods: The Audio/ Podcasts and art here focus on how healthcare professionals and service users could be working together through social media to improve experiences.

Results: Collaboratively, between the RPSG, KDARs and ZtormLabostix Productions, there is the useage of several social media platforms, including four (4) YouTube Channels and two (2) Sound Cloud Channels with over 600 audio/ podcasts, and educational webinars highlighting context supporting service users and service providers surrounding nephrology/ paediatric nephrology, clinical medicine, and biomedical science. Audio/ Podcasts and Art can prompt service user and service providers to join up healthcare.

Conclusions: The RPSG is supports over 10,000 service users amongst adult population and KDARs is supporting near 2,000 service users amongst a paediatric/ young people population. Audio/ Podcasts and Art can help incorporate practice excellence.

The Impact of Pathological Findings of Mitochondrial Disorders in Low-Birth-Weight Infants

Kohei Miyazaki, Yuichi Morimoto, Nao Nagatani, Keisuke Sugimoto. Team Takenoko. *Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan.*

Introduction: Preterm infants with a low birth weight (LBW) show reduced numbers of nephrons at birth and a higher risk of developing kidney dysfunction during their lifetime. They demonstrate oligonephronia and focal segmental glomerulosclerosis (FSGS) lesions in their glomeruli. We examined the association between mitochondrial disorders and the pathological characteristics of LBW-related nephropathy.

Case Description: Methods: We retrospectively evaluated the renal pathology in 6 infants including pairs of twins and 2 LBW infants demonstrating renal dysfunction. In addition to routine staining, the kidney biopsy specimens were analyzed using cytochrome c oxidase subunit IV (COX IV) and transcription factor A (TFAM) staining. Results: FSGS was diagnosed in 2 and oligonephronia in 4 infants. The mean density of glomeruli was 3.8/mm^2 (0.3–7.2) Granular swollen epithelial cells (GSECs), which have previously been reported exclusively in patients with mitochondrial cytopathy, were observed in the distal tubules and/or collecting ducts in all 6 infants. Electron microscopic examination revealed that these GSECs included an increased number of enlarged mitochondria. Furthermore, we observed unbalanced expression patterns of COX IV and low expression of TFAM in the glomeruli and a part of the tubular cells.

Discussion: FSGS, a characteristic feature of glomerular involvement in patients with mitochondrial cytopathy is very commonly observed in LBW infants. In our study, all infants did not show FSGS lesions because a renal biopsy was performed in the early stages of the disease in contrast to previous reports. However, most patients revealed similar pathological changes of mitochondrial cytopathy such as unbalanced expression of TFAM, which plays a role in maintaining the mitochondrial DNA. This finding suggests that these lesions could appear during early childhood, resulting in the development of FSGS in the future. Conclusions: These findings could suggest the application of a new approach targeting mitochondrial DNA to prevent the development of LBW-related nephropathy.

PUB351

Correlation of Serum Creatinine in Pregnant Mothers and Preterm Neonates

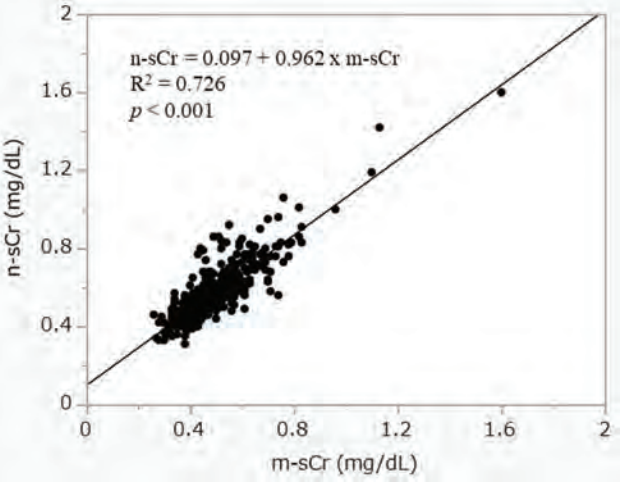
Wataru Shimabukuro,[1] Shogo Nakada,[2] Kohei Shimada,[2] Kazuya Hamada,[1,2] Hideki Goya,[1,3] Noriko Kinjo,[1,2] Tomohide Yoshida,[1,3] Keiko Mekaru,[3] Koichi Nakanishi.[1,2] *[1]Department of Child Health and Welfare (Pediatrics), Graduate School of Medicine, University of the Ryukyus, Nishihara, Japan; [2]Department of Pediatrics, University of the Ryukyus Hospital, Nishihara, Japan; [3]Maternity and Perinatal Care Center, University of the Ryukyus Hospital, Nishihara, Japan.*

Background: Neonatal serum creatinine (n-sCr) in the first few days of life have been reported to correlate with maternal serum Cr (m-sCr). To our knowledge, no regression equation was reported on the correlation between n-sCr after birth and m-sCr before delivery. The purpose of this study is to perform a simple linear regression analysis and to obtain a regression equation indicating the association between n-sCr within 24 hours after birth in preterm neonates and m-sCr within 7 days prior to delivery.

Methods: From March 2017 to October 2022, among 659 preterm neonates treated in the University of the Ryukyus Hospital, cases who died before discharge, cases with multiple births, chromosomal/genetic abnormalities, congenital anomalies of the kidney and urinary tract, severe heart disease, congenital diaphragmatic hernia, intrathoracic lymphangioma, cases whose mother were on dialysis, and cases in which n-sCr and m-sCr were not measured in pairs were excluded. A simple linear regression analysis of all 366 cases and three subgroups (gestational age [GA] ≦27 weeks [n=27], 28-31 weeks [n=60], ≧32 weeks [n=279]) was performed.

Results: In all cases, median (IQR) weeks of GA, birth weight, n-sCr, and m-sCr were 33.9 weeks (32.0-35.1 weeks), 1,901 g (1,575-2,260 g), 0.55 mg/dL (0.47-0.63 mg/dL) and 0.47 mg/dL (0.41-0.56 mg/dL), respectively. The regression equation for all cases and subgroups (GA ≦27, 28-31, ≧32 weeks) was n-sCr=0.097+0.962×m-sCr (R^2=0.726, p<0.0001), n-sCr=0.104+0.949×m-sCr (R^2=0.934, p<0.0001), n-sCr=0.098+0.930×m-sCr (R^2=0.835, p<0.0001), and n-sCr=0.094+0.975×m-sCr (R^2=0.647, p<0.0001), respectively.

Conclusions: This study showed that n-sCr=0.1+m-sCr approximately, regardless of the gestational age. n-sCr at birth in preterm infants reflect m-sCr and should not be used to determine the presence of kidney dysfunction in preterm neonates.



PUB352

Food Insecurity and Trends in Risk Factors for CKD in Adolescents

Zubin J. Modi,[1] Jenna Kiryakos,[2] Miao Yu,[2] Diane Steffick,[2] Jennifer L. Bragg-Gresham,[2] Tiffany C. Veinot,[5] Brenda W. Gillespie,[3] Meda E. Pavkov,[4] Yoshihisa Miyamoto,[4] Rajiv Saran.[2] *[1]University of Michigan Department of Pediatrics, Ann Arbor, MI; [2]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [3]University of Michigan Department of Biostatistics, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]University of Michigan School of Information, Ann Arbor, MI.*

Background: The high prevalence of obesity and prediabetes in adolescents in the United States is a public health concern. We hypothesize that food insecurity may promote the burden of these conditions, which can increase chronic kidney disease (CKD) risk. We explored trends in obesity and prediabetes and how they may differ by food insecurity.

Methods: We included 10,013 adolescents (12–17 years) from the National Health and Nutrition Examination Survey (2001–March 2020). HbA1c of 5.7%–6.4% and/or a random glucose of 140–199 mg/dL defined prediabetes. Body mass index (BMI, kg/m^2) percentiles were calculated from BMI Z-scores corresponding to the participants' sex and age (in months) from the 2000 Centers for Disease Control and Prevention growth charts. A BMI percentile >95% defined obesity. Household food security classified as marginal, low, or very low were deemed food insecure. Analyses applied sample weights.

Results: The mean age was 14.5 (SEM=0.02) years, 51% were male, and 90% had health insurance. The sample included 58% Whites, 14% Blacks, 14% Mexican Americans, 8% non-Hispanic Others, and 7% Other Hispanics. Nearly 20% had obesity and 5% had prediabetes. During 2001–March 2020, the prevalence significantly rose for obesity (17%–22%) and prediabetes (2%–7%). Obesity and prediabetes prevalence were higher in food insecure adolescents (Figure). Among those, over 30% were obese and 9% were prediabetic in 2017–March 2020 (Figure).

Conclusions: Food insecurity may exacerbate rising trends of CKD risk factors like obesity and prediabetes in adolescents. Identifying food insecure adolescents may improve healthy food access and lower risk for CKD in adulthood.

Mexican Wolf Hunting! Epidemiological Report on Mexican Lupus Nephropathy in Pediatric Age

Edgar Eduardo Morales-Montes,[1,2] Linda F. Perez,[1,2] Luis A. Aparicio Vera.[1,2] *[1]Benemerita Universidad Autonoma de Puebla, Puebla, Mexico; [2]Hospital para el Niño Poblano, Puebla, Mexico.*

Background: Childhood-onset systemic lupus erythematosus (cSLE) exhibits worse survival rates than its adult counterpart, primarily due to renal involvement. The epidemiology of renal involvement in cSLE is poorly understood in Latin America. Existing research primarily relies on studies involving both adults and children. In contrast, our study provides the unique epidemiological panorama of an exclusively pediatric center.

Methods: Retrospective, analytical, cross-sectional study. Patients diagnosed with cSLE in our center in the period 2000-2020 for men and 2010-2020 for women were included. No patient was excluded. The data on renal involvement correspond to the time of diagnosis.

Results: Renal involvement occurred in 100% of men against 82.1% of the women (p=0.032). Only 60.9% of the men and 28.4% of the women underwent biopsy (p=0.005). Urinalysis reported a higher frequency of granular casts (p=0.019) and proteinuria (p=0.006) in men than women. Furthermore, estimated glomerular filtration rate was significantly lower in men (p=0.002). Finally, when comparing the frequency of renal involvement, no difference was found between our sample and countries with the highest renal involvement reported in pediatric literature.

Conclusions: cLSE in the Mexican population is, at the renal level, among the most aggressive reported in literature; with males being the most affected group. Despite the high frequency of renal involvement, biopsy was underutilized.

Poor Sleep Efficiency and Shorter Sleep Duration Associated with Increased Blood Pressure in Pediatric Hemodialysis Patients

Jonathan S. Chawla,[1] Molly R. Vega,[2] Shweta S. Shah,[1] Kevin Kaplan,[1] Jessica Geer,[2] Cortney T. Zimmerman,[2] Ayse Akcan Arikan,[1] Sarah J. Swartz,[1] Leyat Tal,[1] Poyyapakkam Srivaths.[1] *[1]Baylor College of Medicine Department of Pediatrics, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Cardiovascular disease (CVD) is the leading cause of death in pediatric (ped) patients (pts) with end-stage kidney disease (ESKD). Hypertension (HTN) is an important modifiable risk factor for CVD in this population. Poor sleep is associated with HTN in adults and ped pts without other comorbidities. We previously used actigraphy (ATG) to demonstrate high prevalence of poor sleep efficiency (SE) and inadequate total sleep time (TST) in a cohort of ped hemodialysis (HD) pts. We hypothesize poor sleep per ATG will be associated with elevated BP in ped pts on HD.

Methods: In this prospective cohort study, pts 8-18 years on HD for > 3 months were asked to wear an ActiGraph™ accelerometer on non-dominant wrist for one week, logging sleep/wake times daily. Oscillometric BP obtained pre-, mid-, & post-HD and indexed to 95%ile. Pts considered hypertensive if pre-HD BP was >95% for age, sex, and height per published AAP standards. Central BP taken with SphygmoCor® EM3 and compared to published standards and cutoffs for age, sex, and height.

Results: 21 pts completed ATG. 62% male, mean age 15±2.9yr, mean HD vintage 1±1.1yr, mean BMI Z-score -0.63±1.4. All pts had three 240min HD sessions per week. 43% (n=9) met AAP definition of HTN per pre-HD oscillometric BP. Central BP was elevated in 48% (n=10). Pre-HD BP persistently correlated with shorter TST and lower SE by Pearson's R (see Table). Paired T-tests comparing pts with and without HTN by office BP showed that pts with HTN slept 1.65hr less than pts without HTN on nights following HD (p=0.035).

Conclusions: This is the first study assessing sleep quality and its association with HTN in ped HD pts, using actigraphy to provide objective measures of sleep quality and duration. The significant association of shorter TST and lower SE with higher BP represents actionable changes that can reduce CV mortality by improving sleep hygiene and identifying patients that warrant polysomnography to assess for obstructive sleep apnea.

		Index of office SBP by 95%ile		Index of DBP by office 95%ile	
Total sleep time (TST)	HD day	R = -0.31	p = 0.18	R = -0.25	p = 0.29
	Non HD day	R = -0.52	**p = 0.02***	R = -0.51	**p =0.02***
	Average	R = -0.50	**p = 0.02***	R = -0.40	p = 0.07
Sleep efficiency (SE)	HD day	R = -0.40	p = 0.08	R = -0.51	**p = 0.02***
	Non HD day	R = -0.38	p = 0.10	R = -0.32	p = 0.18
	Average	R = -0.44	**p = 0.04***	R = -0.48	**p = 0.03***

PUB355

Etiologic Associations, Clinical Characteristics, and Histologic Findings of Children with Acute Interstitial Nephritis

Ke Xu, Fang Wang. *Peking University First Hospital Department of Pediatrics, Beijing, China.*

Background: To explore the etiologic factors of acute interstitial nephritis (AIN) in Chinese children confirmed by kidney biopsy, and its correlation with clinical and pathological manifestations.

Methods: The clinical and pathological manifestations of 21 children diagnosed with AIN in Peking University First Hospital from January 2012 to December 2022 were retrospectively analyzed. According to final diagnosis, the patients were divided into Tubulointerstitial nephritis and uveitis (TINU) group and non-TINU group. T-test, Mann-Whitney U test and Fisher's exact probability test were used for comparison between the groups.

Results: Twenty-one patients were included in this study, accounting for 1.6% of kidney biopsy patients during the same period. Ten cases (48%) were characterized as TINU, 2 cases (10%) were associated with Sjögren syndrome, 1 case (5%) was likely drug induced, and 1 case (5%) was sarcoidosis. The etiology for 7 cases (33%) remained unclear. Compared with the non-TINU group, the TINU group had a higher proportion of uveitis (P=0.024) at the same time with AIN,higher proportion of late-onset uveitis (P<0.05) diagnosed after the onset of the AIN, and a lower proportion of metabolic acidosis (P=0.024). There was no significant difference between the TINU group and the non-TINU group in other clinical manifestations, laboratory tests, and pathological findings. In the TINU group, three cases had preceding infection within 20 days before onset; four patients had received at least one antibiotic due to fever or respiratory tract infection symptoms before renal biopsy: one case received NSAIDs and one case received traditional Chinese medicines in concert with antibiotics.

Conclusions: The proportion of TINU in children with AIN in China is likely to be severely underestimated, given that the clinical manifestations, laboratory tests, and pathological findings of TINU in children are similar to those caused by other causes of AIN. Therefore, it is recommended that all pediatric AIN patients suspected to be related to medication, infections, or unclear etiology undergo a systematic eye examination and receive regular follow-up visits from ophthalmologists for at least one year.

PUB356

Clinical Characteristics of Pediatric ANCA Vasculitis

Binil Mathew Jacob,[1] Jacqueline Kruglyakova,[2] Lois J. Arend,[2] Olga Charnaya.[2] *[1]Ben-Gurion University of the Negev Faculty of Health Sciences, Beer-Sheva, Israel; [2]The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Pediatric ANCA-associated glomerulonephritis (AAGN) is a rare diagnosis with limited data detailing the natural history or clinical characteristics that can be used for clinical prediction at the time of diagnosis.

Methods: Single-center retrospective cohort of pediatric patients diagnosed with ANCA vasculitis by kidney biopsy between 2002 – 2022. Patient characteristics were compared by Wilcoxon-rank sum and chi-squared for continuous and categorical variables, respectively. Survival analysis was done with Kaplan-Meier and Cox proportional hazards for a composite outcome of end-stage kidney disease or death.

Results: Seventeen patients (<20yr) were diagnosed with AAGN, accounting for 1.4% of all pediatric kidney biopsies performed during the study period. Median (IQR) age at diagnosis was 15 (12-17) years old with most patients diagnosed with pANCA disease, and a slight female preponderance. There was no statistically significant difference in the extra-renal symptoms at presentation between the cANCA and pANCA groups, however a trend towards more patients with pANCA presenting with fever. Seven of 17 patients (41%) reached the composite end-point at a median time of 7 yrs. Increased proteinuria and C4 complement level were associated with increased hazard of ESKD/death HR 2.29 (1.00 – 5.28) and HR 1.28 (1.06 – 1.53), respectively.

Conclusions: Pediatric AAGN is a rare diagnosis in pediatric patients presenting during adolescence and associated with significant morbidity. Proteinuria and higher C4 at diagnosis were associated with increased hazard of ESKD/Death. Role of C4 in this disease is unclear and warrants further exploration in a larger cohort.

Obinutuzumab in Recurrent Focal Segmental Glomerulosclerosis After Pediatric Kidney Transplantation: A Case Report

Marina Vivarelli, Luca Antonucci, Francesca Semeraro, Manuela Colucci, Martina Riganati, Raffaella Labbadia, Andrea Cappoli, Francesco Emma, Isabella Guzzo. *Ospedale Pediatrico Bambino Gesu, Roma, Italy.*

Introduction: Recurrence of immuno-mediated forms of FSGS after kidney transplant occurs in about 30% of cases and is often associated with poor outcome. Currently, standardized therapeutic protocols are not available. Possible options are plasmapheresis, rituximab, cyclosporine, and immunoadsorption. We describe a pediatric FSGS recurrence treated with the 2nd generation humanized anti-CD20 antibody obinutuzumab.

Case Description: A 3 years-old child with multidrug-resistant FSGS underwent a related-donor kidney transplant. Twelve hours after anastomosis, he developed a severe anuric FSGS recurrence (Fig.1a), treated with high doses of steroids, cyclosporine, rituximab, and plasmapheresis, with poor response. About 3 weeks later, obinutuzumab was given as rescue therapy. One week after drug infusion, proteinuria became sub-nephrotic (48 mg/dL), and kidney function normalized (Fig.1a). After about 7 months on plasmapheresis and standard immunosuppression, proteinuria was absent with a subsequent reduction in plasmapheresis' frequency. A complete and lasting depletion of total CD19+ and memory CD19+CD27+ B cells was maintained for more than 12 months after obinutuzumab infusion (Fig.1b). About one year after transplant, plasmapheresis was discontinued. One month later, in parallel with B-cell reappearance, low-grade proteinuria reappeared (Fig.1a). Therefore, a second rituximab infusion associated with plasmapheresis was planned.

Discussion: To our knowledge, this is the first case of pediatric post-transplant FSGS recurrence treated with obinutuzumab, which determined remission and long-lasting B-cell depletion. Further clinical trials are needed to establish the real efficacy of this approach.

Ravulizumab De Novo in Pediatric Patients with Atypical Hemolytic Uremic Syndrome (aHUS): First Worldwide Cases

Alvaro Madrid Aris,[1] Pedro Arango Sancho.[1,2] *[1]Hospital Sant Joan de Deu, Barcelona, Spain; [2]Pediatric Cancer Center Barcelona, Barcelona, Spain.*

Introduction: Ravulizumab is a long-acting C5 inhibitor that has recently demonstrated its effectiveness for the control of hemolytic uremic syndrome compared to eculizumab, allowing average annual infusion times (up to 70 percent less). There is still no evidence in the literature of naive treatment with this drug in pediatrics. Our objective is to present the first two pediatric cases worldwide using de novo Ravulizumab (in the onset of the disease and post-kidney transplant).

Case Description: 13-year-old girl with history of bloody stools, vomiting and compromise of consciousness with TMA, AKI III evolves to anuria and convulsive episode requiring corticosteroid boluses, 6 plasmapheresis sessions and 4 intermittent hemodialysis. Normal ADAMTS- 13, negative direct Coombs and decreased complement. Due to persistent TMA and requirement of renal replacement therapy (RRT), ravulizumab was started with a loading dose (2400mg) and a second one after 2 weeks. The need for RRT ceased with improvement of hemolysis and renal function. Genetic:CFHR3-CFHR1 deletion. Case 2:7-year-old girl in chronic hemodialysis secondary to aHUS (CD46 mutation) was admitted for kidney transplant from a living donor. Low-intermediate immunological risk and high CMV infectious risk. Induction treatment: Basiliximab, tacrolimus, mycophenolate and steroids. First dose of Ravulizumab was infused the day before transplantation (900mg), well tolerated. The patient has had a favorable evolution of renal function with normal creatinine value at discharge. Protein/Creatinine urine ratio increased to a maximum of 8mg/mg (negative DSA levels). The option of renal biopsy was discarted due to a decrease in proteinuria. She received second dose after 2 weeks, remain stable with no data on recurrence of her underlying disease today.

Discussion: Ravulizumab was satisfactory both in the acute phase of the disease and in the immediate post-transplantation. In the first case we observed a functional recovery from the first dose with no notable adverse effects up today, as in post-transplant patient, maintaining a good control of TMA despite more spaced dosing (8 weeks). The inclusion of this drug in the therapeutic arsenal opens a new safe treatment route in pediatric patients with aHUS.

PUB359

Tolerance and Pathologic Tonsillar Findings Change in Intractable Immunoglobulin A Vasculitis (IgAV) with Nephritis in Two Child Cases

Nao Nagatani, Kohei Miyazaki, Yuichi Morimoto, Keisuke Sugimoto. Team Takenoko. *Kinki Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osakasayama, Japan.*

Introduction: Background Several studies have reported that regulatory T (Treg) cells are critical for maintaining tolerance in immunoglobulin A nephropathy (IgAN). We herein report the tolerance changes and the pathologic tonsillar features in 2 cases (a 12-year-old girl; ISKDC grade IVa and a 14-year-old girl; grade IIIb) with intractable IgAV nephritis who underwent tonsillectomy for disease control. Serum CD4-positive and CD25-positive cells, and Foxp3 levels were detected. In addition, immunohistochemical staining for tonsillar CD4, CD8, HLA-DR, and cytokeratin was performed.

Case Description: Outcomes Additional tonsillectomy decreased proteinuria and they achieved partial clinical remission after this treatment. Serum CD4-positive and CD25-positive cells were elevated in one case, but Foxp3 levels showed no apparent change in the two cases. T-cell nodules were enlarged by infiltration of HLA-DR-positive cells. Histopathological findings of tonsils showed infiltration with both CD4-positive and CD8-positive cells was prominent in interfollicular areas. Cytokeratin staining showed that the layer of crypt epithelium was replaced by squamous epithelium.

Discussion: Take-away lesson The efficacy of tonsillectomy for IgAN is thought to be due to the regulation of tolerance abnormalities. Replacement from the layer of crypt epithelium implies the involution of lymphoepithelial symbiosis. The distribution of CD4 and CD8 is characteristic in the tonsils of those with IgAN. These pathologic findings in IgAV nephritis patients suggest the existence of a similar tolerance abnormality in the tonsils of those with IgAV nephritis. Our results may help to clarify intolerance in IgAV nephritis, although further studies are necessary to clarify the clinical efficacy of tonsillectomy for IgAV nephritis patients.

PUB360

A Boy with Henoch-Schönlein Purpura Nephritis and Mutations in CD151

Zihua Yu,[1] Yulin Zhang.[1,2] *[1]Department of Nephrology, Rheumatology and Immunology, Fujian Children's Hospital, College of Clinical Medicine for Obstetrics & Gynecology and Pediatrics, Fujian Medical University, Fuzhou, China; [2]Department of Pediatrics, Jinjiang Municipal Hospital, Jinjiang, China.*

Introduction: Glucocorticoid (GC) and immunosuppressants (IS) have been found to be effective on treating Henoch-Schönlein purpura nephritis (HSPN). The children with HSPN may be with genetic defect when they don't respond to GC and IS. Here we report a boy with HSPN, who didn't respond to GC and IS, carried mutations in the *CD151* gene.

Case Description: A 15-year-old boy with no family history of kidney disease was admitted for evaluation of recurrent proteinuria in 2022. He initially presented with abdominal pain and purpuric rash on his bilateral lower legs in 2014, and developed recurrent proteinuria. His first renal biopsy tissues in 2018 revealed HSPN with mesangial deposits of IgA together with IgM by immunofluorescence technique. However, his proteinuria was negative to 3+ for many years although he used mycophenolate mofetil and prednisone. The second renal biopsy was performed in 2022, and the renal tissues revealed focal segmental glomerulosclerosis (FSGS) with no evidence of immunocomplex deposition. A homozygous mutation in the *CD151* gene, c.606C>A, p.Y202*, 52, was identified using whole-exome sequencing in the boy, and the same heterozygous mutation was in his parents. Then, the boy was treated with a combination of benazepril and losartan, and his proteinuria reduced to 1+ - 2+.

Discussion: The boy with HSPN, based on his abdominal pain, purpuric rash on his bilateral lower legs, proteinuria and first renal pathology, didn't respond to mycophenolate mofetil and prednisone, so we performed the second renal biopsy. The second renal pathology revealed FSGS with no evidence of immunocomplex deposition, which is inconsistent with HSPN, therefore we suspected the boy may be with genetic defect. A homozygous missense mutation in the *CD151* gene identified in the boy confirmed our hypothesis. CD151 encoded by the *CD151* gene is implicated in the integrity of basement membranes in kidney, skin and inner ear. Mutations in the *CD151* gene can cause isolated proteinuria and FSGS as well. The patients with mutations in *CD151* and nephrotic syndrome have no reponse to GC and IS, which could explain that the boy had persistent proteinuria for many years with treatment with both mycophenolate mofetil and prednisone. In conclusion, the children with HSPN is necessary to detect genetic defect when they don't respond to GC and IS.

PUB361

Implementing a Structured Transition from Pediatric to Adult Care Can Impact Clinical Outcomes in Young Adult Kidney Transplant Recipients

Brian Coburn, Clarkson Crane, Elizabeth G. Ingulli. *Rady Children's Hospital San Diego, San Diego, CA.*

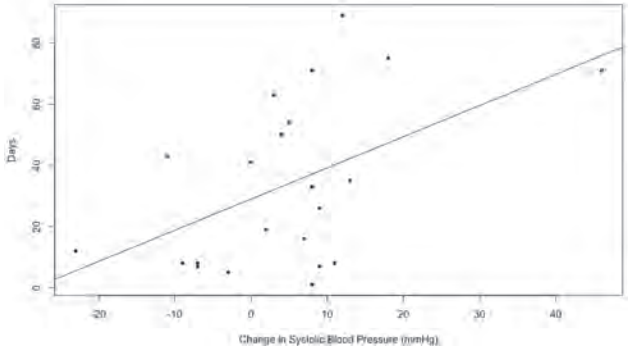
Background: The transition period between pediatric and adult care is a challenging time marked with high risk and vulnerability, and is described as the period with the highest rate of graft loss in young adult kidney transplant recipients. Data are limited regarding HCT outcomes, but some studies suggest improvements in patient outcomes with a structured transition protocol.

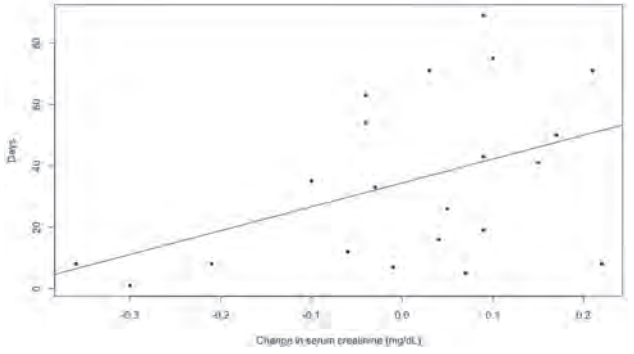
Methods: A retrospective chart review of patients who transitioned from Rady Children's Hospital San Diego (RCHSD) to UC San Diego (UCSD) transplant clinic from the years 2020-2023 is being performed to examine metrics such as change in creatinine

and blood pressure during this period of transition. We will look at outcomes following the implementation of our transitions program which includes strutted transition-specific visits to assess and address individual areas of need before they transition.

Results: Our initial study population consists of 24 patients, 50% female. The data show a weak positive correlation between days from last RCHSD clinic visit and first UCSD clinic visit and blood pressure elevation that is not statistically significant (rho=0.393, p=0.071). The data show a weak positive correlation with an increase in the number of days between last RCHSD clinic visit and first UCSD visit and increasing creatinine which is not statistically significant (rho=0.399, p=0.073).

Conclusions: Further research will be conducted to determine if an established kidney transplant transitions program can decrease gaps in care and improve outcomes in young adult patients with a kidney transplant.





PUB362

Horseshoe Kidney with Childhood Recurrent Urinary Tract Infection: A Harbinger of CKD Progression and Opportunity for Interventions

Arianna S. Moss,[1,2] Catherine T. Pham,[1,2] Ekamol Tantisattamo.[1,3] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]University of California Irvine School of Medicine, Irvine, CA; [3]Nephrology Section, Department of Medicine, Tibor Rubin Veterans Affairs Medical Center, Veterans Affairs Long Beach Healthcare System, Long Beach, CA.*

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT) constitute the most common malformations diagnosed prenatally and account for most chronic kidney disease (CKD) in children. We report a case of a woman with childhood recurrent urinary tract infections (UTIs) who was incidentally diagnosed with a horseshoe kidney in adulthood complicated by advanced CKD.

Case Description: A 62-year-old woman with non-nephrotic range proteinuric stage 4 CKD secondary to CAKUT was referred for kidney transplant evaluation. From age 6 months to 12 years old, she experienced recurrent UTIs and persistent borderline elevated blood pressure yet was never seen by a pediatric nephrologist. At age 52, she was found to have abnormal kidney function during a pre-operative laboratory procedure, and an abdominal and pelvic MRI showed an atrophic right kidney, bilateral nephrolithiasis, bilateral renal cysts, and a horseshoe kidney (Figure 1). While the frequency of UTIs decreased, with the most recent episode of UTI 5 years prior, her eGFR had progressively declined from 24 to 16 ml/min/1.73 m^2 over a 5-year period.

Discussion: Although one-third of patients with horseshoe kidneys are asymptomatic and are incidentally diagnosed in adulthood, our patient presented with kidney complications early in life that necessitated further investigation by her pediatrician and transfer to adult care. Pediatricians play a vital role in the early diagnosis and management of CAKUT and need to recognize the prodromal signs, including low birth weight, recurrent UTIs, and hypertension. Recurrent UTIs during childhood should prompt a search for CAKUT and early therapy to prevent CKD and improve patient health outcomes. Moreover, patients with CAKUT can benefit from a continuum of care by a multidisciplinary team.

PUB363

AKI with COVID-19 Infection due to Drug Interaction of Tacrolimus and Nirmatrelvir/Ritonavir

Eun jeong Ko, Chul Woo Yang. *The Catholic University of Korea, Seoul, Republic of Korea.*

Background: The mortality of SARS-CoV-2 infection of kidney transplant recipients(KTR) is higher than that of general population. Nirmatrelvir(NR) is a good option for outpatient-based antiviral treatment by reducing mortality.

Methods: However, NR is metabolized mainly by cytochrome 3A4(CYP3A4), which also metabolize calcineurin inhibitor(CNI). Hence, t co-administration of these two drug could results in drug interaction increasing serum tacrolimus(TAC) level almost 50 times. We report serial three cases of KTR prescribed NR with/without AKI.

Results: In case 1, the patient took these two drug together, inducing acute kidney injury(AKI) due to CNI toxicity. After discontinuation of TAC, renal function was recovered. Contrastively, in case 2, three days of simultaneous administration of NR and TAC led to AK, progressed even though discontinuation of TAC. Intravenous hydration with cessation of TAC improved renal function. In case 3, patient was informed to stop TAC for 5 days with NR initiation, resulting harmless to renal function with stables serum TAC concentration after NR taking.

Conclusions: Instruction for patient for drug interaction of TAC with NR is important for KTR.

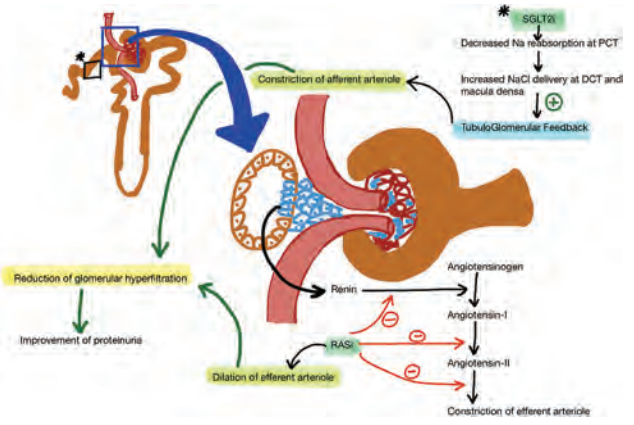
SGLT2 Inhibitors in Membranous Nephropathy: Worthy of Consideration?

Sehajpreet Kaur, Sulekho Egal, Iktej S. Jabbal, Fernando M. Abanilla.
AdventHealth Sebring, Sebring, FL.

Introduction: SGLT2i have encouraging evidence supporting their benefits beyond diabetic kidney disease, as seen in DAPA-CKD and EMPA-KIDNEY trials as well as case reports on IgA nephropathy and Alport syndrome. We describe the early results of SGLT2i therapy in 2 patients with membranous nephropathy (MN), which, we believe, has not yet been reported in the literature.

Case Description: A 67-year-old type 2 diabetic female with CKD stage 3b, PLA2R negative MN, sepsis, and AKI, developed increasing proteinuria (baseline 1.6 to 3.2 g/g UACR) despite irbesartan therapy. The addition of 10 mg empagliflozin daily improved UACR to 3.1 from 3.2 g/g over 5 days of hospitalization. A 68-year-old non-diabetic male who presented with scrotal edema, chronic bilateral leg swelling, and massive proteinuria of 8.8 g/g UPCR was diagnosed with nephrotic syndrome with PLA2R negative MN on renal biopsy. Increasing UPCR to 12.5 g/g prompted the addition of 10 mg empagliflozin daily after optimisation of lisinopril to 40 mg daily. However, 2 months of follow-up resulted in worsening of proteinuria to 15.8 g/g. For both patients, proteinuria serological workup was negative with workup for malignancy pending.

Discussion: As illustrated in Image 1, SGLT2i can synergize with RASi to improve proteinuria, which warrants their exploration in MN. While patient 1 had significant improvement in renal function over 5 days of treatment but empagliflozin could not be continued due to clinical inertia, patient 2 improved clinically but had an early negative response to proteinuria despite 2 months of dual therapy with empagliflozin and lisinopril. An underlying unidentified malignancy or other causes of secondary MN could be attributable. Our case series was limited by small sample size, medication non-adherence, and absence of long-term follow-up. Nonetheless, this calls for the medical community's attention to explore the use of SGLT2i in MN and other proteinuric non-DKD using prospective, randomized controlled trials.



PUB365

Baclofen Toxicity in Patients with ESRD on Hemodialysis (HD)

Ashraf A. Suliman, Irtiza Hasan, Ronald L. Mars, Charles W. Heilig.
University of Florida College of Medicine - Jacksonville, Jacksonville, FL.

Introduction: Baclofen, a commonly prescribed muscle relaxant is a GABA agonist with potential toxicity in patients with CKD.

Case Description: We report three cases of potential Baclofen toxicity in patients with ESRD on HD. The 1st case was a 68-year-old female with PMH of DM, HTN & ESRD on HD, presented with a fall associated with altered mental status (AMS) & inability to move both right extremities, a GCS of 6 & intubated. Home medications included Carvedilol, Doxazosin, Gabapentin (300 mg BID), Hydralazine, Baclofen (5 mg TDS) & Nifedipine. Brain CT without acute abnormality but MRI revealed a small 3 mm left parieto-occipital lobe subdural hematoma with no mass effect or intercurrent hemorrhage with no plan for intervention. The 2nd case was a 50-year-old male with PMH of HTN, CVA, Paroxysmal A Fib & ESRD on HD, presented with AMS, GCS of 15 & no intracranial abnormality. Home medications included Amlodipine, Baclofen (10 mg BID), Carvedilol, Losartan & Sevelamer. Another case of a 66-year-old male with PMH of HIV, HTN, ESRD on HD, transverse myelitis with lower extremity weakness, presented with AMS. Initial workup was negative. Clinical status later improved. However, a week later he became disoriented & unable to follow commands after he was started on baclofen 10 mg bid for muscle spasms. Workup was inconclusive. All of the above cases had no other potential causes for AMS including infection or any signs of uremic encephalopathy other than use of Gabapentin by one of the patients. In the first two cases, patients had missed a couple of dialysis (HD) sessions. Baclofen toxicity was suspected in all cases, exacerbated by missed HD treatments in two cases. There was marked improvement of mentation soon after resumption of HD.

Discussion: Baclofen is a lipophilic compound which is primarily absorbed in the GI & largely excreted by the kidneys. Baclofen toxicity is rare in the general population. It manifest rapidly in patients with impaired renal function who receive this medication. AMS is one of the major manifestations of toxicity, developing with as little as a single dose. However, due to small molecular weight, low volume of distribution & relatively low protein binding, Baclofen is easily dialyzable. Although no medical inhibitor of Baclofen toxicity is available, hemodialysis was effective in treating this condition here, and is the preferred therapeutic modality.

PUB366

Suspecting and Treating Toxic Alcohol Ingestion: A Case of Incorrect Management of Ethylene Glycol Poisoning in the Community Healthcare Setting

Harold G. Jarrell, Jonathan Martinez, Fazal Khan. *St. Francis-Emory Healthcare, Columbus, GA.*

Introduction: Poisonings by the toxic alcohols (methanol, ethylene glycol) can present with nonspecific symptoms but delays in treatment increase the risk of irreversible organ damage and death. Measurement of serum concentrations of the toxic alcohols would be ideal for establishing a diagnosis and monitoring treatment, but obtaining these serum concentrations in a timely fashion is not feasible in the community hospital where this patient presented. Consequently, treatment with the antidote must be given expediently if only suspicion is high.

Case Description: A 37 year old female with an vague psychiatric history presented to the ED with acute respiratory failure and altered mental status. The patient was somnolent and her mental status deteriorating. Presenting labs were significant for leukocytosis with left shift, high anion gap metabolic acidosis w AG of 64, hypocalcemia, hyperkalemia, high serum osmolal gap of 12, high serum osmolality of 305, benign urinalysis, and UDS positive for cocaine. Toxic alcohol levels were ordered but would not return for several

days due to the lab's lack of liquid/gas chromatography. Nephrology was consulted and recommended early emergent intermittent hemodialysis in the setting of severe acidemia, hyperkalemia, and AKI. Fomepizole was never given.

Discussion: A high anion gap metabolic acidosis of unknown cause, acute kidney injury, and an increased serum osmolal gap established a high suspicion for toxic alcohol ingestion early in this patient. Nephrology appropriately initiated intermittent hemodialysis urgently, however the administration of fomepizole was deferred pending a definitive diagnosis via serum concentration of toxic alcohols using high pressure liquid chromatography. This result was not available to providers for several days as is often the case in small community hospitals. Delays in treating toxic alcohol poisonings lead to worse outcomes, therefore therapy with the antidote should be initiated rapidly when unexplained high anion gap metabolic acidosis with high osmolal gap is present, as was the case with this patient. To improve treatment outcomes there should be a standard treatment algorithm agreed upon by each hospital as to when fomepizole should be administered without a definitive diagnosis.

PUB367

Prevalence, Clinical Profile and Risk Factors of Cefepime Induced Neurotoxicity among Chronic Kidney Disease Patients in a Tertiary Hospital in Southern Philippines

Ann Kristine S. Serenina- Martin, Karen Ann Querequincia. *Southern Philippines Medical Center, Davao City, Philippines.*

Background: Cefepime induced neurotoxicity is a clinically diagnosed adverse event that presents in vast array of neurologic symptoms, from mild cognitive and behavioural changes to seizure and coma. Although a highly recognized clinical adverse event the diagnosis and standard clinical criteria is still lacking. We aimed to characterize the clinical profile and possible associated risk factors of cefepime induced neurotoxicity among Filipino chronic kidney disease patients.

Methods: This is a retrospective, case control study of adult chronic kidney disease patients treated with Cefepime in a tertiary hospital in Southern Philippines from January 2020 to June 2022. Patients who were treated with cefepime with new onset neurologic deteriotion were included while those with baseline neurologic abnormality or alternative cause for neurologic symptoms as ruled out by additional diagnostic tests were excluded. The Naranjo scale was utilized to establish the likelihood of causality.

Results: A total of 263 medical charts were reviewed but only 132 cases were included. Majority of patients were on hemodialysis (126), six of whom developed neurotoxicity. The overall prevalence of cefepime induced neurotoxicity is 4.5%, with higher prevalence rate at 10% among patients given non renally adjusted dose. The median age of patients with CIN was 54 ± 14, predominantly females (5 vs 1). Half of the cohort presented with agitation while the other 50% had decreased level of consciousness. The appearance of symptoms has a latency period of 5 days following initiation of therapy. Five (5) patients responded to hemodialysis and discontinuation of cefepime, while one (1) patient responded to appropriate dose adjustment. Resolution of symptoms was observed 2 days after providing therapy. All patients (6) recovered without neurologic deficit. Binary regression analysis identified female gender (OR 9.65) and congestive heart failure (OR 12.1) increased the likelihood of cefepime neurotoxicity.

Conclusions: Overall prevalence of cefepime induced neurotoxicity is comparable to preceding studies, with higher prevalence rate among patients who were given non-renally adjusted dose. Possible additional risk factors for CIN were female gender and heart failure.

PUB368

Higher Intragraft Granzyme-B+ and PhosphoSMAD-3+ Cell Staining Are Associated with Inflammatory Interstitial Fibrosis and Tubular Atrophy in Renal Allograft Recipients

Narayan Prasad, Brijesh Yadav, Vinita Agrawal. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Inflammatory **I**nterstitial fibrosis and tubular atrophy (i-IF/TA), a histological lesion reported in late biopsy, is associated with graft survival. Cytotoxic T cell secrets Granzyme-B, cleaves cytoskeleton protein, and activates pro-IL-1β, and TGF-β into their active form, leading to inflammation, fibrosis, and apoptosis of cells. Association of Granzyme-B+ cytotoxic T cell and phospho-SMAD-3 expression has been not studied in i-IF/TA in depth. We studied the circulating and intragraft Granzyme-B+ cytotoxic T cell and fibrosis pathway mediator p-SMAD-3+ cell in renal transplant patients with biopsy proven i-IFTA.

Methods: The circulating frequency of CD3+CD8+Granzyme-B+ cytotoxic T (CTLc) was measured by the flowcytometry; serum and PBMCs culture supernatants Granzyme-B and cytokines TGF-β, IL-1β level by the ELISA, Intragraft Granzyme-B mRNA transcript expression by the RT-PCR and Granzyme-B$^+$, pSMAD-3$^+$ cell were analyzed by immunohistochemistry. Independent T-test for continuous variables and Pearson correlation were applied for different variables.

Results: The circulating frequency of cytotoxic-T cell ($CD3^+CD8^+$Granzyme-B^+) in SGF vs i-IF/TA was (27.96±4.86 vs 23.19±3.85%, p=0.011), $CD3^+$T cell was (66.08±6.8 vs 65.18±9.35%; p=0.68), $CD3^+CD8^+$T cell was (37.29±4.11 vs 34.68±5.43%; p=0.28). Serum Granzyme-B level was in SGF vs IF/TA was (100.82±22.41 vs 130.32±46.60, p=0.038 pg/ml), serum TGF-β level was (367.50±31.50 vs 318.81±48.39, p=0.005), IL-1β level was (49.14±17.03 vs 63.69±23.13, p=0.076). Intragraft Granzyme-B mRNA expression in SGF vs i-IF/TA was (1.01±0.048 vs 2.10±1.02-fold, p<0.001). Granzyme-B^+ cell/mm^2 count was (0.40±0.69 vs 2.20±1.27; p=0.001). Intragraft phosphorylated SMAD-3$^+$ cell was (3.70±1.82 vs 6.73±3.21; p=0.008). The intragraft Granzyme-B+ cell was positively correlated with pSMAD-3+ cell (r=0.315, p=0.047). The frequency of circulating CTLc was negatively correlated with urine proteinuria (r= -0.51, p<0.001), serum creatinine (r= -0.28, P=0.007) and eGFR (r= -0.28, p=0.037). While urine proteinuria was positively correlated with serum Granzyme-B level (r= 0.343, p=0.001), intragraft Granzyme-B mRNA transcript expression (r= 0.38, p<0.001).

Conclusions: Higher intragraft Granzyme-B^+ Cytotoxic T-cell and phosphoSMAD-3 positive cells are associated with i-IF/TA in RTRs.

PUB369

Identification of APOL1 with Probe-Independent Polymerase Chain Reaction (PCR) Method

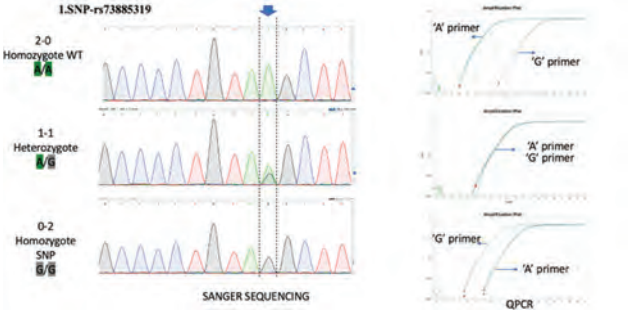
Murat Dogan,[1] Anshul Bhalla,[1,2] Amandeep Bajwa,[1] Canan Kuscu,[1] Cem Kuscu.[1] Transplant Research Institute - James D Eason Transplant Institute, UTHSC, Memphis TN. *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]Methodist University Hospital, Memphis, TN.*

Background: Circulating APOL1 in plasma can kill the Trypanosoma brucei which causes sleeping sickness found in sub-Saharan Africa. 2 coding sequence variants G1/G2 in APOL1 actually provide more resistance against a subtype. These variants are specifically presented in African-American population group and found to be associated with increased risk of chronic kidney disease. In this study, we determine a method to identify risk variants using prob-independent qPCR approach in transplant patients with high African-American population group. Additionally we want to explore available haplotypes for all variants with respect to transplant outcome.

Methods: We used PBMNC samples from patients and perfusate samples from donor to isolate DNA. Perfusate samples during transportation of organ from donor to recipient patient and blood samples of recipients were collected. DNA is isolated using SDS lysis buffer and proteinase K. After DNA isolation, constructed primers were used to amplify APOL1 gene segment including SRA domain (which is including the possible regions of G1/G2). Sanger sequencing were used as control to detect any SNPs and deletions of APOL1 risk variants. Special constructed primers were used to quantify either SNP mutations or wild type and deletion or wild type.

Results: 97 % of our donors do not have APOL1 risk alleles, however we have very high percentage (27% 2 Risk Allele, 33% 1 Risk Allele) of APOL1 variants in patients. We have limited numbers to compare all risk allele haplotypes. With new kidney transplant patients, we may estimate haplotypes effect on long term outcomes. In short term period, there is not much significant differences compared the groups.

Conclusions: Our technique allows clinicians and researchers in the field to be able to identify ApoL1 genotyping with QPCR in 3-4 hours. Retrospective studies might allow to compare these findings with long term allograft rejection and can create an estimation for patients for early-late stage transplant outcomes with haplotype evaluation.



PUB370

Unveiling a Protective Role of Endomucin in Endothelial Cells During Kidney Allograft Rejection

Ahmad Halawi,[1,2] Connor J. O'Brien,[1] Tamara Merhej,[1] Nour K. Younis,[1] Rania El Fekih,[1] Sacha A. De Serres,[3] Jamil R. Azzi.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Mount Auburn Hospital, Cambridge, MA; [3]Universite Laval, Quebec, QC, Canada.*

Background: Understanding the role of endothelial cells in autoimmune and alloimmune mediated kidney diseases promises to develop more targeted therapies. Our single nuclei RNA sequencing (snRNA seq) identified an unexpected role for endothelial cells in cellular rejection. Notably, we reported a novel role of endomucin (EMCN), a molecule known for its anti-adhesive and anti-inflammatory properties, in kidney allograft rejection.

Methods: We performed snRNA seq of human kidney allografts with non-rejection, borderline rejection, and T-cell mediated rejection (TCMR) based on Banff criteria. We performed pathway analysis focusing on immune and endothelial cells. As validation for our endothelial cells findings, we isolated and cultured blood outgrowth endothelial cells (BOECs) from different patients using our optimized protocol (S Beland et al., JASN 2023). We stimulated BOECs with INFg, TNFa, and allogeneic PBMCs. We studied the expression of EMCN and ICAM1 over time under different stimulation using Flow cytometry.

Results: Our snRNA seq showed that TCMR samples had enrichment for allograft rejection pathway, suggesting that our borderline sample reflects an early rejection. Hence, this allows for studying the early stages of rejection. Pathway analysis of endothelial cells (ECs) of borderline and non-rejecting samples showed that focal adhesion and IFN-gamma pathways were significantly enriched compared to TCMR. Major genes related

to focal adhesion were upregulated in borderline, suggesting a role of focal adhesion as a physical obstacle to immune migration. ECs upregulated EMCN in early rejection, suggesting a critical role in protecting against T cell adhesion and infiltration in the allograft. EMCN was then downregulated when rejection advanced. Similarly, in our in vitro model, activated human ECs downregulated the constitutive expression of EMCN when stimulated with allogeneic PBMCs, contrary to ICAM1, which was significantly upregulated. This observation was not seen when ECs were stimulated by IFNg and TNFa, suggesting that the effect of immune cells on ECs is not mediated by these cytokines.

Conclusions: Our data showed that late during rejection, focal adhesion and EMCN are downregulated in endothelial cells suggesting a possible role in protecting the graft from immune invasion and rejection.

PUB371

Variability in Commensal Gut Microbiota Associated with Tacrolimus Metabolism in a Longitudinal Kidney Transplant Cohort Study

Guillaume C. Onyeaghala,[1,2] Duy Vo,[1] Henry Madden,[2] Julia J. Munoz,[2] Bryan P. Brito Sanchez,[1] Moataz Mohamed,[2] Abdelrahman Saqr,[2] Sarah Elmer,[1] Christopher Staley,[2] Casey R. Dorr,[1,2] Levi Teigen,[2] Baolin Wu,[3] Weihua Guan,[2] Rasha El-Rifai,[2] William S. Oetting,[2] Arthur J. Matas,[2] Pamala A. Jacobson,[2] Ajay K. Israni.[1,2] *[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]University of California Irvine, Irvine, CA.*

Background: Tacrolimus (TAC), an immunosuppressant used with mycophenolate mofetil (MMF), has a narrow therapeutic range which is associated with outcomes in kidney transplant recipients (KTRs). Evidence of an association with the gut microbiome and TAC metabolism is emerging. Multiple commensal gut bacteria, including *Faecalibacterium prausnitzii*, have been shown to metabolize TAC to a less potent metabolite through keto-reductase activity. We hypothesized that the gut microbiome of KTRs would exhibit high variability in TAC metabolizers.

Methods: We evaluated the relative abundance of 22 known gut microbial TAC metabolizers in a cohort of 40 KTRs who had stool samples collected at 60 and 120 days post-transplant (tx). All KTRs received oral MMF and TAC twice daily. Microbiota were characterized by sequencing the V4 variable region of the 16S rRNA gene.

Results: We detected 15 out of 22 previously reported tacrolimus metabolizers among the gut microbiota, with the most abundant being *Faecalibacterium prausnitzii* at 7.54% average relative abundance at 60 days post-tx (range 0.06% - 22.15%) (FIG 1A) and 7.95% (range 0.02 – 20.45%) at 120 days post-tx (FIG 1B). We did not find a statistically significant change in relative abundance of these organisms between 60 and 120 days post-transplant (Fig 1C, P> 0.05 for all microbiota). Overall, these 15 TAC metabolizing microbiota accounted for 15.6% (range 0.1 – 41.1%) of the total gut microbiome composition at 60 days, and 14.1% (range 0.2 – 37.6%) at 120 days.

Conclusions: The gut microbial composition of TAC metabolizers exhibits high variability post-tx, with *Faecalibacterium prausnitzii* as a predominant member. The association between the abundance of these organisms and TAC interpatient variability should be studied to understand the unexplained variation in TAC concentrations among KTRs.

Donor LIMS1/GCC2 Region Is an Important Determinant of Allograft Kidney Response to Ischemia and Reperfusion

Yasar Caliskan, Kento Kurashima, Meghan M. Unes, Edward L. Portz, Kana N. Miyata, David S. Brink, Bahar Bastani, John C. Edwards, Krista L. Lentine, Ajay Jain, Mustafa Nazzal. *Saint Louis University, Saint Louis, MO.*

Background: *LIMS1* rs893403-G influences LIMS1 and GCC2 expression and associated with kidney allograft rejection. Using non-utilized human kidneys, we investigated the effects of ischemia reperfusion injury (IRI) on LIMS1, GCC2 and associated gene expressions by normothermic machine perfusion (NMP) model and compared with cold storage (CS).

Methods: Non-utilized deceased donor kidney pairs underwent 6-hr NMP (n=6) and CS (n=6). Perfusion, biochemical, and histologic parameters were recorded. NMP was compared with CS in paired donor kidneys using simulated transplantation with allogeneic red blood cells, followed by assessment of the gene expression. Genotyping for rs893403 variant performed by Sanger sequencing.

Results: Kidneys were successfully perfused with evidence of urine output (Table 1). Transcriptomic analyses showed induction of GCC2, HIF-1α and KIM-1 expression in kidneys with rs893403-GG genotype compared to kidneys with rs893403 AG/AA (rejection risk donor genotype) under NMP (p=0.017, p<0.001 and p=0.17, respectively) (Fig.1a-b). Change in GCC2 expression after 6 hrs of NMP was significantly correlated with change in LIMS1 (r=0.94, p=0.005), KIM1 (r=0.83, p=0.04), TGF-β (r=0.89, p=0.019) and HIF-1α (r=0.943, p=0.005) expressions. Change in GCC2 expression during NMP was not correlated with donor characteristics including age, KDPI, Remuzzi score, cold ischemia time and urine output.

Conclusions: NMP significantly increased the GCC2 expression in kidneys with *LIMS1* rs893403-GG variant. Donor rs893403 genotype is important in the transcriptomic response to IRI and understanding the interaction between LIMS1, GCC2 and HIF-1α will help to develop genotype and pathway specific therapies for rejection.

Cognitive Improvement in ESRD Patients After Renal Transplantation: A Prospective Observational Study

Simran Sawhney,[1] Vijay K. Kher.[2] *[1]Medanta The Medicity, Gurgaon, India; [2]Epitome Kidney and Urology Institute, New Delhi, India.*

Background: Although there is a well-established survival benefit of renal transplant, the evidence of its effect on cognitive function is limited and not entirely consistent. Up to 30 - 70 % of end stage renal disease patients are reported to have cognitive deficits. The etiology of cognitive impairment in chronic kidney disease patients is multifactorial. Kidney transplantation can correct the metabolic derangements and eliminate the fluid and osmotic shifts that patients can experience on dialysis; however, cognitive impairments still persist post-transplant. Further research is warranted to better understand the impact of kidney transplant on a wide array of cognitive domains.

Methods: 100 patients, age between 18 to 60 years who underwent renal transplantation in Medanta Hospital, India were prospectively studied from September, 2021 to December 2022. The aim was to determine the proportion of patients showing cognitive improvement 3 months and 6 months post renal transplant using Montreal Cognitive Assessment (MoCA) and to find the cognitive domains which show significant improvement 3 months and 6 months post transplant.

Results: Proportion of patients showing cognitive improvement 3 months and 6 months post transplant was 26% and 56%, respectively. The mean MoCA score (out of total of 30) at pre transplant, at 3 months and 6 months post-transplant was 24.08 ± 3.08, 24.32 ± 2.90 and 25.28 ± 3.05, respectively. Mean MoCA score after 6 months of transplant, when compared to the mean score at pre transplant level was found to be statistically significant (p value <0.001). Delayed recall showed significant improvement 3 months and 6 months post-transplant (p value- 0.016 and < 0.001 respectively).

Conclusions: Significant cognitive improvement was seen 6 months post renal transplant. Delayed recall showed significant improvement 3 months and 6 months post transplant.

Montreal Cognitive assessment (MoCA) score		Mean Difference	Std. Error	p value	95% Confidence Interval for Difference

LECT2 Amyloidosis in Allografts

Jonnathan O. Cázares Lara, Orlando E. Falcón-Antonio, Maria J. Ballesteros Alfaro, Enrique A. Alamo Capula, Eduardo Carrillo Maravilla. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Introduction: LECT2 deposits are subclinical. The risk of transplanting an allograft with this condition is not zero.

Case Description: In 2011, a 26-year-old male was found with a serum (Cr) of 1.6 and a protein in the urine of 2.37 g/day. The histopatology reported glomerulonephritis IgA. Years later, patients brother was ruled out as a donator due to proteinuria, and the cross-match test was performed with the patients father. In 2022, he underwent kidney transplant but two months later due to proteinuria, a renal graft biopsy was performed that showed mild LECT2 FIAT amyloidosis.

Discussion: LECT-2 is a chemotactic factor for neutrophils. It is involved in cell proliferation, inflammation, immunomodulation, and carcinogenesis. Its gene is located in a chromosome that harbors a cluster of genes involved in immune regulation. LECT-2 is produced in the liver and increases in response to proinflammatory stimuli such as hepatic steatosis. ALECT2 can be found in association with other types of amyloidosis, plasma cell dyscrasia, membranous nephropathy, carcinomas, or autoimmune disease. Amyloidosis restricted to the kidney is uncommon. The 88%%–92% of cases reported are in Hispanics. The median age is 69 years old, and men and women are equally affected. The proteinuria could be not present in 21%, nephrotic range proteinuria was noted in only 33%, and when it is present, you need to consider concomitant nephropathy (as IgA nephropathy), and end-stage renal disease ranges from approximately 30% to 40%. In our patient, the time for a novo or recurrent amyloidosis is too short. The Hispanic background in the father and the proteinuria in his brother, lean us towards a case of familiar donor-derived ALECT2. It has been reported that ALECT2 does not interfere with the allograft function.

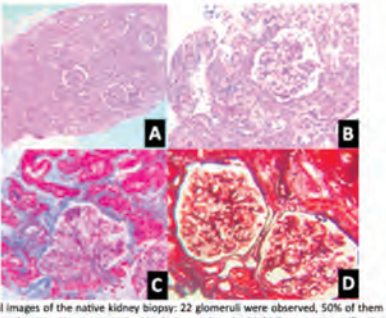

Figure 1- Histopathological images of the native kidney biopsy: 22 glomeruli were observed, 50% of them with global sclerosis and 8.7% with segmentary sclerosis, since panoramic view in image A and with high power magnification (B) as well as slight mesangial expansion and proliferation (D). In the interstice it was characterized a moderate fibrosis state (calculated as 30%) but it was not observed any deposition of material out of collagen with Masson's trichrome stain (C).

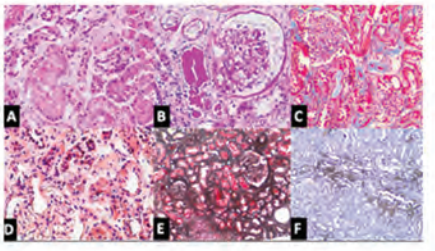

Figure 2.- Histopathological images of transplanted kidney: a rarefactive, well-defined globular deposition was observed since the initial H&E stain (A) evaluation with low power magnification lens (x 100); the rest of routine histochemical stains, remarked the presence of this material, but mostly with PAS (B) and Masson trichromic stain (C), present within the glomerular basement membrane, mesangium, intertitium and arteriolar walls. With the amyloid specific stain, Congo red (D), it highlights the presence giving a brick red aspect, nonetheless the polarized light microscope showed negative birefringence. The characterization of the deposition material with immunohistochemistry analysis for LECT2 amyloid (Abcam, OTI2A11) resulted positive (E).

PUB375

Risks and Harms of Minimizing Total Immunosuppression in Stable Kidney Transplant Recipients

Bruno Watschinger, Bernhard Gromann, Peter Hlavac, Robin Ristl, Bettina Kroyer, Katharina Hohenstein-Scheibenecker. *Medizinische Universitat Wien, Wien, Austria.*

Background: While minimizing steroids or calcineurin inhibitors was advocated to be advantageous for kidney transplant outcomes, the effect of total cumulative immunosuppression on patient /allograft survival has not yet been evaluated. In our retrospective single center study, we investigated the long-term impact of cumulative immunosuppression exposure in a large cohort of patients with stable graft function.

Methods: 887 stable patients (s-creatinine <2 mg/dl @ 1 yr and stable GFR slope in the preceding 3 months, transplanted from 1/2000 to 12/2012 and followed exclusively at our institution; median follow-up 6, 3 (1-15,3) yrs were studied. Graft function and immunosuppressive (IS) therapy were recorded at 84.140 patient visits. Individual drug exposure was calculated by grading each drug (no=0, low=1, medium=2, high dose=3) and then adding single drug grades (in mono, dual, triple therapies) to a cumulative score that represents a low (0-3), intermediate (4-6) or high (7-9) total IS exposure load. This load, calculated over time, was used in adjusted Cox-regression models with time-dependent covariates, together with Kaplan-Meier survival analysis. Patient/allograft survival was compared between the 3 exposure groups.

Results: 84 of these stable patients (9.5%) lost their graft during the observation period, 89 patients (10%) died with a functioning graft. In single drug analysis, variant exposure levels of steroids or calcineurin inhibitors did not show differences in graft and patient survival. Conversely, cumulative exposure was associated with differentiated outcomes. An intermediate total IS load yielded the best graft survival, while patients with low (HR = 4.68; CI 1.6-13.9, p=0.005) or high (HR = 2.08; CI 1.2-3.6, p=0.008) cumulative IS exposure had a significantly elevated risk for graft failure. Patient survival did not differ between the groups.

Conclusions: Analyzing the effects of single drugs does not capture the risk for graft loss in patients with stable allograft function @ 1 yr. High and low cumulative total immunosuppression exposures are independent risk factors for graft failure but do not impact patient survival. Thus, the degree of total, cumulative immunosuppression should be carefully considered, whenever individual immunosuppressants are minimized.

PUB376

Successful Treatment of Kidney Transplant Rejection in the Setting of COVID-19 Infection

Mohammad Atari,[1] Michael B. Kuperman,[2] Prathap Simhadri,[3] Bushra Syed,[1] Sanjana Kapoor,[1] Pradeep Vaitla.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Arkana Laboratories, Little Rock, AR; [3]AdventHealth Daytona Beach, Daytona Beach, FL.*

Introduction: Kidney transplant recipients are at increased risk for complications from COVID-19 infection. There are no guidelines for rejection treatment in the setting of COVID-19 infection.

Case Description: A 44-year-old male with a history of living donor kidney transplant underwent a kidney biopsy due to rising creatinine that showed features suspicious for chronic active antibody-mediated rejection and acute vascular rejection 2A, with De novo class II DSAs emergence. The patient tested positive for COVID-19 and was asymptomatic with normal CXR. Cycle threshold was 21 indicating high viral replication, nucleocapsid antibodies were negative, but he had a suitable spike antibodies titer. Rejection was treated with pulse steroids, IVIg, and immunosuppression optimization. COVID-19 was treated with three doses of remdesivir. Two weeks later, the patient was treated with thymoglobulin, PLEX, and rituximab. Follow-up biopsy showed no rejection, and creatinine improved.

Discussion: Kidney transplant rejection with active COVID-19 infection is challenging and requires an individualized approach. Rejection treatment may lead to clinical deterioration, but untreated rejection may lead to graft failure. COVID-19 infection severity can be assessed by symptoms, chest images, cycle threshold to assess viral replication, anti-nucleocapsid antibodies as a marker for natural immunity against COVID-19, and spike antibodies as a response to vaccination. Dexamethasone is used in severe COVID-19 infection, rejection treatment with a reduced dose pulse steroids, IVIg, and PLEX, with remdesivir to prevent the progression of COVID-19 infection, seems to be relatively safe. If the patient remains stable, more intense rejection therapies can be commenced two weeks after COVID-19 diagnosis.

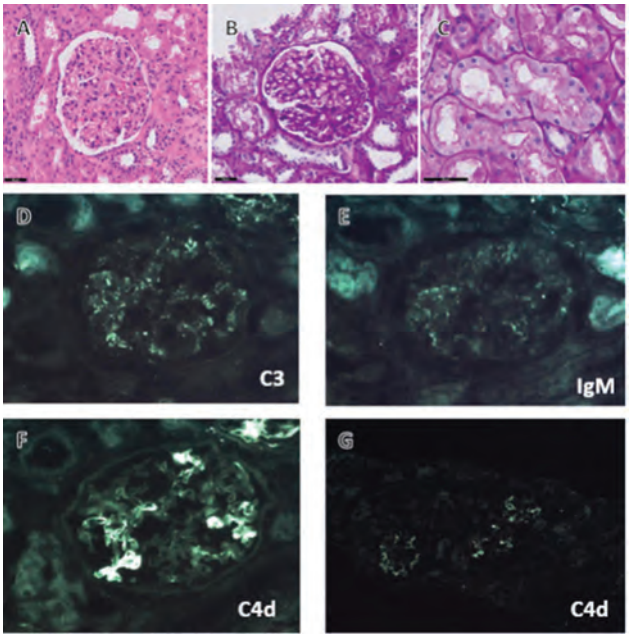
Recurrent Atypical Hemolytic Syndrome (AHUS) Manifested by Atypical Postinfectious Glomerulonephritis

Eun jeong Ko, Chul Woo Yang. *The Catholic University of Korea, Seoul, Republic of Korea.*

Introduction: Atypical hemolytic uremic syndrome(aHUS) is a rare disorder of the complement pathway, Results of kidney transplantation(KT) in patients with genetic predisposition to aHUS bring about recurrent disease.

Case Description: A 45-aged male kidney transplant recipient was admitted for rapid deterioration of graft function after 1 month from KT. Serum creatinine raised from 1.43 mg/dl to 2.72mg/dl within 2 weeks. Furthermore, anemia(serum Hb 6.8g/dl), thrombocytopenia(platelet 72 x 109 /L), elevation of LDH(458mg/dl), decrease of haptoglobin(<10mg/dl), and microangiopathic hemolytic anemia(MAHA) were also found, suggesting TMA. He has kept on deflazacort, tacrolimus, and mycophenolate mofetil, so firstly tacrolimus was switched to rapamune, still no improvement. Shiga toxin was negative and ADAMTS13 activity was negative. Even though plasmapheresis for 7 times, no clinical response were seen. Graft biopsy pathology reported as postinfectious glomerulitisnephritis, inconsistent with clinical feature. on revewing his chart retrospectively, he had malignant hypertension with severely decreased renal function (serum Cr 23.35mg/dl), anemia (Hb 5.7g/dl), elevated LDL (304mg/dl), and decreased complement 3(56mg/dl), 9 years ago, his first visit to clinic. Also, native kidney biopsy revealed TMA, still we missed futher evaluation. Afterall, we performed genetic study for aHUS, next generation sequence(NGS) revealed heterozygous mutation for complement factor I(CFI)(c.119A>C), pathogenic for aHUS, confiremd recurrent aHUS after KT.

Discussion: Clarifying primary renal disease of transplant candidate is crucial, especially screening for genetic study for aHUS.



Microscopy and immunofluorescence of kidney biopsy in case patient

Should We Treat Asymptomatic Bacteriuria (ASB) in Post-Transplant Patients: A Systematic Review and Meta-Analysis

Thiratest Leesutipornchai,[1,2] Noppawit Aiumtrakul,[1,2] Manasawee Tanariyakul,[1,2] Chinnawat Arayangkool,[1,2] Christie H. Izutsu.[1] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Hawaii Residency Programs Inc, Honolulu, HI.*

Background: Urinary tract infections (UTIs) are the most common infectious complication in kidney transplant recipients (KTRs). Therefore, routine screening for and treatment of asymptomatic bacteriuria (ASB) is a common practice in post-kidney-transplant surveillance. However, little is known about the impact of antimicrobial therapy on ASB in KTRs. Some data reports overtreatment of ASB increases the risk of Clostridioides difficile infection in this population. This study aimed to investigate whether antibiotics reduce the risk of UTI in KTR with ASB.

Methods: We searched MEDLINE, EMBASE and Cochrane Library from inception to March 2023. Included studies were RCTs or cohort studies that compared the incidence of UTI among treated ASB group versus untreated ASB group, using the random-effects to calculate risk ratios (RR) and 95% confidence intervals (CIs). Secondary outcomes included rate of graft rejection, hospitalization and mortality.

Results: Five RCTs and 6 cohort studies were included in the analysis with a total of 1750 subjects (699 treated ASB group and 1051 untreated ASB group). Our study showed that there was no statistically significant difference in incidence of UTI between the ASB group with treatment and ASB group without treatment (pooled RR 1.07, 95% CI 0.77-1.48, p=0.682, I2=16.9%). Secondary outcome analysis revealed none of the outcomes were significantly different between these two groups including acute graft rejection rate (pooled RR 0.79, 95% CI 0.43-1.48, p=0.464, I2=0.0%), hospitalization rate (pooled RR 1.34, 95% CI 0.99-1.81, p=0.061, I2=23.8%), and all-cause mortality (pooled RR 1.20, 95% CI 0.96-1.51, p=0.110, I2=0.0%).

Conclusions: There is no difference of incidence of UTI, acute graft rejection rate, hospitalization rate, and all-cause mortality rate among treated ASB group versus untreated ASB group in kidney transplant recipient patients.

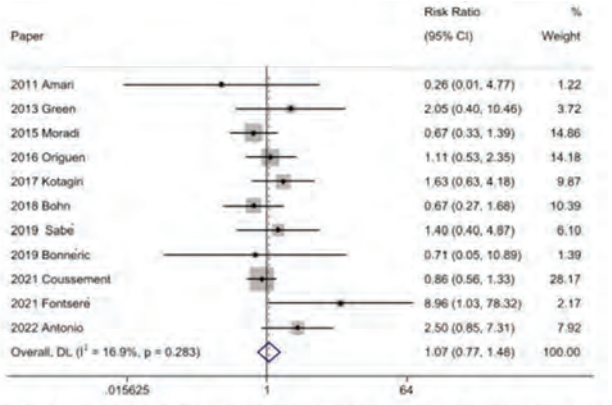

Figure 1: Forest plot of the included studies comparing the incidence of UTI among treated ASB group versus untreated ASB group (p = 0.682)

Successful Treatment of Ganciclovir-Resistant Cytomegalovirus (CMV) in Kidney Transplant Patients by Reduction of Immunosuppression and Withdrawal of Valganciclovir

Allifia Abbas, Mysore K. Phanish. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Introduction: Cytomegalovirus (CMV) is a common opportunistic infection after kidney transplant, causing increased morbidity, mortality and graft loss. Resolution of infection requires both antiviral drugs and the host immune response. Ganciclovir (GCV) and Valganciclovir (VGCV) are currently 1st-line treatment, though GCV-resistant (GCV-R) CMV is increasingly reported. Treatment of GCV-R CMV infection involves use of the 2nd-line agents Cidofovir, Foscarnet or Maribavir. We propose a therapeutic strategy combining withdrawal of GCV with reduction in immunosuppression in refractory CMV replication.

Case Description: We describe 3 patients who underwent kidney transplantation from CMV-positive deceased donors. One seronegative recipient received VGCV prophylaxis. All developed CMV syndrome at a mean 40 days post-transplant. One patient developed chronic inflammatory demyelinating polyneuropathy, requiring intravenous immunoglobulin. In all cases mycophenolate mofetil was withdrawn and eGFR-adjusted doses of GCV or VGCV commenced. A persistent/increasing viral load following > 4 weeks treatment led to resistance testing. A *UL97* mutation was identified in all cases, one patient also demonstrating a *UL54* mutation. GCV-R was diagnosed at a mean 160 days post-transplant. Given persistent viremia despite prolonged, adequate dose treatment, we decided to withdraw VGCV and monitor CMV viral load. By a mean of 60 days following VGCV withdrawal we could show a 50% reduction in viral load with no detectable GCV-R virus and ultimately a complete and sustained virological clearance in all patients.

Discussion: We demonstrate that in patients treated for CMV but with persistent GCV-R viremia without evidence of invasive CMV disease, VGCV withdrawal may be a therapeutic strategy, rather than commencement of problematic second-line drugs. GCV resistance is an adaptive process, we propose that discontinuing GCV significantly reduces selection pressure for *UL97* mutants. As resistance mutations are often not maintained in the population after drug cessation, we believe this allows immune clearance of the CMV, perhaps aided by the improved white cell count on withdrawal of VGCV, as seen with our 3 cases. This approach potentially promotes re-population with 'wild type' GCV-sensitive strain which may respond to subsequent challenge with GCV.

PUB380

Tacrolimus-Induced Post-Transplant (pT) Thrombotic Microangiopathy (TMA)

Emad A. Odeh. *Al-Bashir Hospital, Amman, Jordan.*

Introduction: TMA is a well-recognized complication that may occur at any time pT. It has a significant impact on graft and patient survival. TMA may result from the recurrence of the original disease. Or denovo. Patient presentation with pT-TMA varies from localized form affect the graft and diagnosed only by biopsy, to systemic form, consist of hemolysis, thrombocytopenia and kidney injury. Here we present a case of TAC induce pT-TMA which was treated by changing tacrolimus(TAC) to cyclosporin(CsA) with plasma exchange(PLEX).

Case Description: A 33 year-old male known to have HTN, ESKD on regular hemodialysis for 9-months, before receiving living-related kidney transplant from his mother. Pre-transplant preparation yielded HLA matching of 50%. Negative lymphocytotoxicity by CDC. Induction with basiliximab (2 doses), pulse steroid, extended-release TAC(0.2mg/kg/day) and mycophenolate mofetile (MMF)720mg*2. The early pT period went smoothly without delay in graft function. On the 4th pT day platelate count(PLT) dropped to 135000 with stable hemoglobin(hb), creatinine(Cr), and blood film(BF) showed NO schistocytes. The MMF dose decreased to 360mg*2, after which the PLT normalized and the patient was discharged with a Cr of 1.2mg/dl on:TAC-trough level of 17ng/ml. MMF360mg*2 and prednisone. After 2 weeks:the patient suffered from hand tremor, TAC-level:15. Stable Cr, hb and PLT. The TAC dose was decreased, 1 week later the tremor increased despite the TAC level being 10. Further investigation: Cr-2, a drop in hb, PLT(122000), and 30% schistocytes on-BF. The patient was afebrile, urinalysis was normal, negative CMV and BKV. The diagnosis of TMA was made, plan for kidney biopsy and to change TAC to CsA. Later PLT dropped to80000 and Cr became 2.2. Given this situation we considered not to wait biopsy, and plasma exchange was started. After 5 PLEX sessions, the PLT became230000, Cr-1.3, and BF showed less than 4%schistocytes. The biopsy showed borderline cellular rejection. Negative c4d. No glomerulitis, PTC, and no thrombi. 9 months later the patient doing well with Cr of 1.3.

Discussion: The take-home messages are: TMA can occur any time pT.CNI may induce TMA while drug level within therapeutic range. The absence of thrombi in a kidney biopsy sample doesn't exclude renal TMA, so if you've enough data to diagnose TMA, dont't waste time and start treatment immediately. Removal of TAC may not be enough in some cases of TAC-induce TMA, and the addition of PLEX may required.

PUB381

Evaluation of Indications for Genetic Assessment in Living Kidney Transplant Donors and Relevant Canadian Practices in Light of the Current International Guidelines

Somaya Zahran,[1] Ke F. Bei,[2] Aisha Adil,[2] Princess N. Okoh,[2] Ahsan Alam.[1] *[1]McGill University, Montreal, QC, Canada; [2]University of Toronto, Toronto, ON, Canada.*

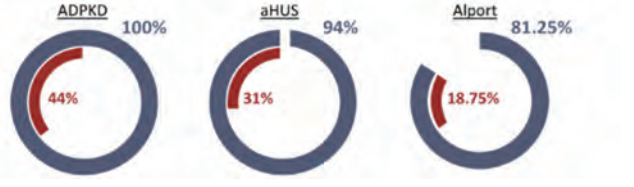
Background: End stage renal disease (ESRD) is a prevalent condition with tendency for familial clustering. Living kidney donor transplantation is a superior treatment option, however, up to 40% of living kidney transplant donors (LKTDs) are biologically related to their recipients which subjects recipients to worse graft survival and donors to higher future risk of ESRD. Genetic testing of potential LKTDs could improve risk assessment and inform safety of donation, however, the strategies to evaluate these donors are still evolving. In this context, the standard use of genetic testing for LKTDs in Canada is unknown.

Methods: International guidelines were reviewed to compare the indications for genetic assessment of LKTDs. Surveys were sent to 25 Canadian adult transplant centers to examine their protocols and relevant practices for LKTDs genetic assessment.

Results: Response rate was 70%. Generally, donor's family history of chronic kidney disease does not preclude donation after informed discussion regarding risks and benefits. Autosomal Dominant Polycystic Kidney Disease, Alport syndrome and atypical Hemolytic Uremic Syndrome are the most frequently encountered conditions. Based on our case scenario questions, most centers assess LKTDs on a case-by-case basis and a minoroity have specific policies for donor genetic evaluation. The current Canadian transplant centers practices generally align with available international guidelines' recommendations. The most cited guidelines are KDIGO, CSN/CST, and Kidney Paired Donation Protocol.

Conclusions: Canadian transplant centers have diverse strategies for genetic evaluation of LKTDs, mostly based on case-by-case assessment. Current recommendations are largely based on expert opinion due to lack of a reliable body of evidence and inefficiency of the current testing modalities. More studies are needed to provide stronger, evidence-based recommendations to ensure safety of donation. Prognostic risk assessment scores could be helpful for better quantification of long term effects of abnormal genetic testing.

Fig 1: Percentage of the most commonly encountered genetic conditions in the Canadian transplant centers [Blue] versus percentage of center having donor evaluation protocols for the same conditions [Red].



PUB382

Impact of Deceased-Donor Characteristics: Outcomes of Donor Kidney Pairs Accepted for Transplantation

Christoph F. Mahler, Christian Nusshag, Claudius Speer, Louise Benning, Matthias Schaier, Markus Mieth, Arianeb Mehrabi, Martin G. Zeier, Christian Morath, Florian Kälble. *Universitat Heidelberg, Heidelberg, Germany.*

Background: To support acceptance decisions in kidney transplantation, deceased-donor based scores are increasingly used. Yet, the performance of these algorithms remains moderate and the impact of donor characteristics is controversial.

Methods: We analysed 52 kidney donor pairs (104 grafts) transplanted in different individuals. Recipients were followed for up to 3 years. Poor function (three-month estimated glomerular filtration rate (eGFR) <30 ml/min) and early graft loss (EGF) were the primary discriminatory factor. We reasoned that a relevant impact of donor variables would result in a high concordance rate of graft failure.

Results: Graft loss was significantly more frequent in recipients with reduced function or failure of the partner graft (Log-rank: p=0.006, Figure 1). This difference remained significant when we adjusted for recipient age, PRA and wait time

(Cox HR: 3,2; 95% CI: 1.06-9.83, p=0.03). Yet, there was no difference between rates of death with functioning graft (p=0.3). Relevant risk factors were donor- and recipient age, donor eGFR and HLA-mismatches.

Conclusions: Our results suggest that in kidney transplantation donor factors have a relevant impact on early transplantation outcomes. The use of donor-based clinical scores could potentially improve acceptance decisions and post-transplant outcomes.

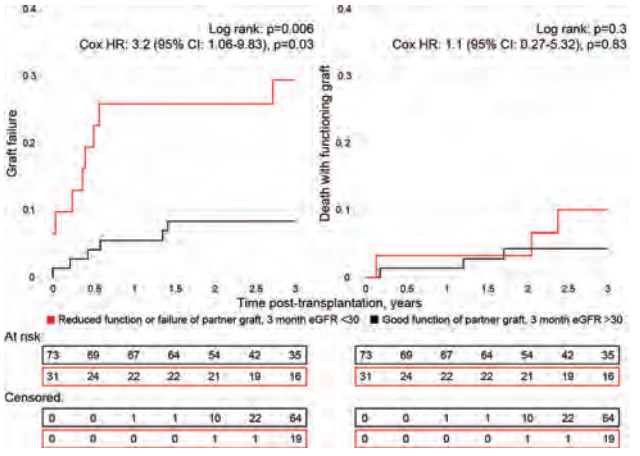


Figure 1: Cumulative incidence of graft failure by partner graft function. For grafts with early reduced graft function (eGFR<30), the incidence of graft failure in the respective partner graft is substantially higher (left panel). In contrast there was no significant difference in death with functioning graft between groups.

PUB383

Clinical Usefulness of Bortezomib-Based Desensitization Therapy in Highly Sensitized Living and Deceased Donor Kidney Transplantation

Hyeran Park, Seunghyeok Choi, Hanbi Lee, Byung ha Chung, Chul Woo Yang. Division of Nephrology, Dept of Internal Medicine. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: The aim of this study is to investigate the usefulness of bortezomib based desensitization (BZB-DSZ) therapy in highly sensitized living and deceased donor kidney transplantation.

Methods: We reviewed retrospectively 20 patients underwent BZB-DSZ protocol, of which 14 were living donor kidney transplantation (LDKT) candidates and 6 were on wait-list for deceased donor kidney transplantation (DDKT) between July 2012 and Nov 2022 in our center. We applied this protocol to LDKT candidates with positive T-CDC (complement dependent cytotoxicity) crossmatch at baseline or refractory to DSZ using rituximab and plasmapheresis (RTX/PP). Among DDKT candidates, we applied this protocol when (i) waiting time ≥ 10 years (ii) panel reactive antibody values ≥ 50% and (iii) previous history of a positive T cell crossmatch with potential deceased donor.

Results: Out of the 20 patients who received the BZB-DSZ protocol in both LDKT and DDKT candidates, 16 (80%) proceeded with transplantation, 1 refused the transplant, and 3 are awaiting for DDKT. Among LDKT candidates, 8 out of 10 (80%) candidates with a positive T-CDC turned negative. Mostly the mean fluorescence intensity (MFI) level of donor specific anti-HLA antibody (HLA-DSA) markedly decreased to target level (MFI<5,000). In four cases that were refractory to RTX/PP based DSZ, the MFI value of HLA-DSA showed a marginal decrease and was identified as HLA-DQ. Among DDKT candidates, the count of strong HLA-DSA (MFI>10,000) mostly decreased after DSZ. Out of them, 3 showed negative T cell crossmatch test to deceased donor, so we could proceed with DDKT. All 16 cases did not show hyper-acute rejection after transplantation and 8 cases (50%) showed biopsy-proven allograft rejection, with an antibody-mediated rejection rate of 87.5% within the first year of transplantation. Currently, overall renal function has been maintained stable through appropriate treatment. Death censored allograft survival during median follow-up duration of 35 months was 93.75%. Out of the 16 transplanted patients, 3 received antiviral treatment for CMV viremia, and 1 of them expired due to pneumonia sepsis.

Conclusions: Bortezomib based desensitization is effective to reduce HLA-DSA and enables highly sensitized patients to take kidney transplantation, and showed acceptable allograft outcomes.

PUB384

Correlation of Tc99m-Diethylene-Triamine-Pentaacetate (DTPA) Clearance to Long-Term Outcomes of Kidney Donors

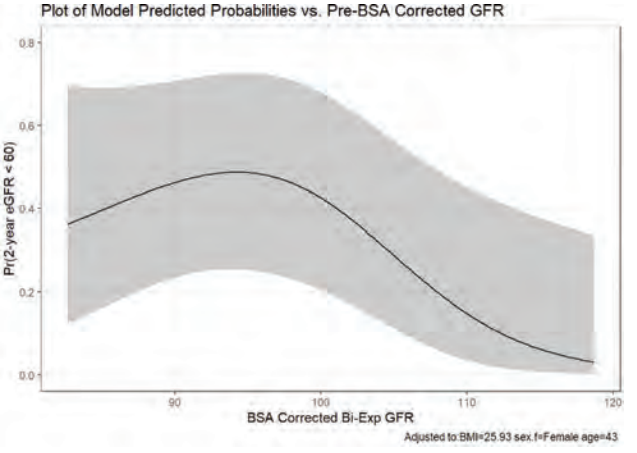
Niketna Vivek, Jared V. Grice, Trey W. Mcgonigle, Shi Huang, Austin M. Hilvert, Hamideh Ale Ali, Beatrice P. Concepcion, Anthony J. Langone, Heidi M. Schaefer, Rachel C. Forbes. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Live kidney donors allow for gold-standard transplantation. Evaluating candidates entails assessment of kidney function. An eGFR <60 ml/min is a contraindication to donation. A method for assessing donors is measured GFR (mGFR) based on radioisotope (Tc99m-DTPA) clearance from the plasma. However, there is little existing literature quantifying the relationship between pre-donation mGFR values to long term donor function.

Methods: This study included all donors (N=107) at one institution (1/17-12/20) with preoperative DTPA-Tc99m and 2 year follow up eGFR. Serum-creatinine eGFR calculations were performed. Pre-donation mGFR for donors with 2 year eGFR above and below 60 ml/min were compared using Wilcoxon rank sum test. A logistic regression model was fitted for the binary indicator of 2-year eGFR < 60 including a nonlinear effect for preoperative mGFR. To visualize the effect of preoperative mGFR on 2-year eGFR, the model-estimated probability (2-year eGFR < 60) was plotted against pre-donation mGFR. A linear regression model on 2-year eGFR was fitted.

Results: Wilcoxon test showed significant differences in pre-donation mGFR values between 2-year eGFR >60 ml/min group compared to the <60 ml/min group (98 vs 83, p<0.001). In the logistic regression model, the effect of mGFR was marginally significant (p=0.065) with evidence for nonlinearity. As pre-donation mGFR increases beyond 95 ml/min, the probability of the patient having a 2 year eGFR <60 decreases (Figure 1). In the linear regression model, pre-mGFR was significantly positively related to the 2-year eGFR (p=0.015).

Conclusions: Current model implies there is a significant decrease in the probability of having eGFR < 60 when pre-donation mGFR begins around 110. Though there is a clear, positive relationship between pre-donation mGFR and 2-year eGFR, more work is required to better understand how mGFR can aid in inclusion criteria for donors.



PUB385

Unexpected Medical Conditions Discovered During Live Donor Kidney Evaluation

Alexandra Lee,[1,2] Christina A. Raker,[1,2] George P. Bayliss,[1,2] Reginald Y. Gohh,[1,2] Basma O. Merhi.[1,2] *[1]Lifespan Health System, Providence, RI; [2]Brown University, Providence, RI.*

Background: Living donor kidney transplantation is the preferred method of treatment for patients with end-stage kidney disease, with greater survival outcomes and graft success rates than deceased donor transplants. Potential living kidney donors (PLKD) are screened medically and psychosocially to ensure donation will not impact their long-term health. Our transplant center has noticed an increasing number of otherwise healthy PLKDs excluded from donation due to a previously unknown condition during the medical evaluation process. Our objective was to characterize newly diagnosed conditions to better understand how to improve living donor kidney transplantations.

Methods: Data was collected by electronic medical record review of PLKDs screened between December 2012 and April 2023, and included age, race, gender, relationship to recipient, and reason for exclusion as well as method of diagnosis.

Results: Of the 223 excluded PLKDs, over half were due to newly diagnosed conditions (Figure 1). The most common conditions were diabetes mellitus, hypertension, and renal issues (Figure 2). Some infrequent yet notable conditions detected were sickle cell trait and horseshoe kidney. The majority of newly diagnosed PLKDs were female (Figure 1).

Conclusions: Over half of excluded PLKDs were diagnosed with new conditions, all of which have severe health consequences if not properly treated. While these results may reflect changing donation criteria, they also raise concerns regarding gaps in primary care in our area.

Funding: Private Foundation Support

Figure 1 shows the outcomes of our center's PLKDs between December 2012 and April 2023.

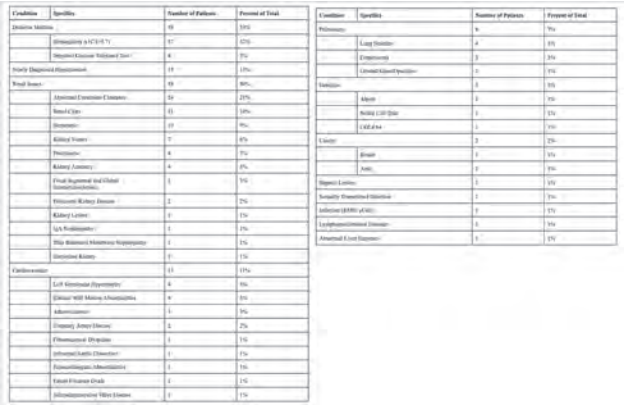


Figure 2 categorizes the newly diagnosed conditions of 115 prospective donors.

PUB386

Relationship Between Prognosis and kt/V After Kidney Transplantation in Peritoneal Dialysis Patients

Young Eun Park, A Young Kim, Kyu-hyang Cho, Jong-Won Park, Jun-Young Do, Seok hui Kang. Dept of Internal Medicine-Nephrology, Yeungnam University Medical Center. *Yeungnam University Medical Center, Daegu, Republic of Korea*.

Background: In dialysis patients, control of kt/v and metabolic acidosis may affect patient outcome. Studies have shown that metabolic acidosis control helps early recovery of renal function after kidney transplantation (KT). However, studies on the correlation with kt/v are rare. We hypothesized that pretransplant kt/v control would affect renal function after KT.

Methods: The subjects were 61 patients who underwent a KT at our hospital during peritoneal dialysis. We calculated the average value of kt/v measured three times before KT. Group A was classified as kt/v 1.7 or higher, and group B was classified as less than 1.7. Primary endpoint was a comparison of serum creatinine levels between the two groups on days 1, 2, 3, 5 and 7 after surgery. Secondary endpoint was to compare urine output and serum blood urea nitrogen levels between the two groups.

Results: The mean age was 54.6±10.1 in group A and 45.8±12.0 in group B. Among the factors that may affect the prognosis after KT, the donor's serum creatinine level and patients' base serum creatinine level and ischemic time showed significant differences between the two groups. There was no difference in serum albumin and blood urea nitrogen levels between the two groups. Serum creatinine improvement after KT was significantly slower in group A than in group B. There was no difference in blood urea nitrogen and urine volume between the two groups.

Conclusions: It was found that the improvement of serum creatinine level after kidney transplantation was rather slow in the group with high kt/v. In the group with high kt/v, donor serum creatinine level was high and the ischemic time was long. These factors seem to have more influence on the prognosis than kt/v itself. Due to the small number of subjects, additional studies on kt/v and the prognosis after KT are needed.

PUB387

Vitamin C Deficiency After Kidney Transplantation: Results of the TransplantLines Biobank and Cohort Study

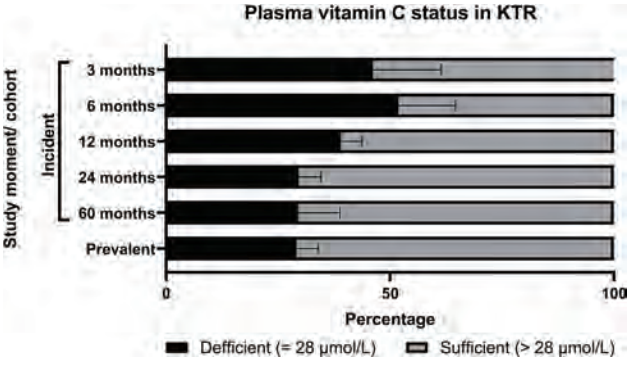
Manuela Yepes Calderon,[1] Yvonne van der Veen,[1] Daan Kremer,[1] Camilo G. Sotomayor,[1,2] Tim J. Knobbe,[1] Michel Vos,[1] Eva Corpeleijn,[1] Martin H. De Borst,[1] Stephan J. Bakker.[1] TransplantLines Investigators. *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Clinical Hospital University of Chile, Independencia, Chile.*

Background: Vitamin C is an essential antioxidant nutrient whose deficiency has been associated with higher mortality and graft failure risk in kidney transplant recipients (KTR). We investigated the trajectory, prevalence, and determinants of vitamin C deficiency post-kidney transplantation.

Methods: Plasma vitamin C was measured in 579 KTR at 3, 6, 12, 24 and 60 months post-transplantation. An additional cohort of 374 KTR (median 8 years post-transplantation) was added to study the long-term determinants of vitamin C deficiency. Deficiency was defined as plasma vitamin C ≤28 µmol/L. Diet was assessed by a 177-item food frequency questionnaire, including data on supplementation.

Results: At inclusion, the 953 KTR were 62% male, mean age 55 years and mean eGFR 55 ml/min/1.73m^2. The intraindividual coefficient of variation of plasma vitamin C during follow-up was 17%. Prevalence of vitamin C deficiency ranged from 52% (6 months post-transplantation) to 29% (prevalent KTR, Fig 1). At ≥12 months post-transplantation, diabetes mellitus was the main clinical characteristic associated with higher risk of vitamin C deficiency (OR 2.30, 95% CI 1.46-3.61). Higher dietary vitamin C was associated with a lower risk of deficiency (OR 0.38, 95% CI 0.24-0.61 per 100 mg/day) and, on average, supplemented KTR had 19 µmol/L higher plasma vitamin C than non-supplemented KTR (p<0.001).

Conclusions: Plasma vitamin C is stable after kidney transplantation with a high prevalence of deficiency among KTR, particularly among KTR with diabetes mellitus. Higher intake of vitamin C, both dietary and supplemented, decreased the risk of deficiency among KTR. Further research is warranted to assess if correcting vitamin C deficiency improves patient and graft survival in KTR.



Prevalence of vitamin C deficient KTR was 46%, 52%, 39%, 30%, 30% and 29% at 3, 6, 12, 24, 60 months post-transplantation and prevalent transplantation, respectively.

PUB388

A Single-Center Case Series of Successful Abdominal Organ Transplantation from SARS-CoV-2-Infected Donors to Uninfected Recipients: Do We Need Rigorous Monitoring?

Mohankumar Doraiswamy,[1] Priyamvada Singh.[2] *[1]Department of Internal Medicine, Mercy Hospital, Fort Smith, AR; [2]Department of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: There is limited documentation of **h**ematogenous transmission of SARS-CoV-2 in nonlung transplants from infected donors to uninfected recipients.

Methods: We analyzed sixteen recipients (7 Liver, 9 Kidney) transplanted from SARS-CoV-2- NAT+ deceased donors from 12/25/2021 to 2/28/2022 who were followed for at least 90 days. Primary outcomes included COVID positivity, allograft loss, and all-cause mortality. Secondary outcomes included biopsy-proven rejection [BPAR], DSAs, DGF, and opportunistic infections. Unlike previous studies, we followed the recipients clinically with the intent to treat if they developed SARS-CoV-2 symptoms.

Results: All donors were SARS-CoV-2 PCR positive 72 hours before donation. No recipients developed SARS-CoV-2 infection. The nadir serum creatinine and eGFR were 1.33 mg/dL and 64 mL/min/1.732 m2 for KTx, respectively. The median ALT was 14.5 IU/L, AST 13 IU/L, and ALP 74 IU/L. Two KTx lost allograft, and one LTx died with a failed allograft. However, this was unrelated to their SARS-CoV-2 positive donor status. One BPAR in the LTx was treated with steroids. No DSAs or BPAR were reported in the KTx. Six KTx experienced DGF, and four are off dialysis. Two KTx developed CMV infection due to an error in reporting the CMV serostatus by the donor center. We did not do serial testing for SARS-CoV-2 by PCR, imaging, or cycle threshold score pre- or post-transplant for donor/recipient and had comparable outcomes to previous studies.

Conclusions: Due to the low risk of transmission, serial testing might not be necessary and thus, could be reciprocated at small-volume transplant centers.

PUB389

Epstein-Bar Virus (EBV)-Associated Plasmacytoma/Congophilic Lambda Light Chain (LC) Casts Four Months After Kidney Transplant Causing Death of the Patient

Ravi K. Thimmisetty,[1] Thilagavathi Venkatachalam,[2] Thelmo Fidel Ernesto Barrantes Ramirez.[1] *[1]New Mexico State University, Albuquerque, NM; [2]The University of Texas Southwestern Medical Center, San Antonio, TX.*

Introduction: 66-yr-old lady with out any prior hematological history admitted with allograft failure 4 months after having donation after brain death (DBD) kidney transplant. Work up showed EBV associated plasma cell neoplasm(PCN) with monoclonal LC in kidney. Her disease course was rapidly deteriorated despite hemodialysis and chemotherapy to multiogran failure, shock and death.

Case Description: 66-yr-old lady with h/o diabetic kidney disease status post DBD kidney transplant admitted with renal failure and nephrotic range proteinuria. Admission vitals temp 98.4 f, BP 131/67 mmHg, HR 96 bpm, RR 20. Physical examination on admission was unremarkable. Laboratory results on admission H and H 11.0 mg/dl and 34 % Cr 5.8 mg/dl, urine protein/creatinine 26.41 g/g and urine microalbumin/creatinine 11.53 g/g, free Lambda light chain 983.2 mg/dl, kappa chains 1.54.SPEP M-component 0.35 gm/dL, free lambda light identified in the gamma region. IgG low at 480. Renal biopsy showed acute tubular injury with congophilic lambda light chain intratubular casts. EBV PCR 160 K IU/mL, 5.2 log 10 IU/mL. Bone marrow biopsy showed 1% plasma cells, lambda light chain restricted with positive EBV. Flow cytometry showed monoclonal plasma cells with positive for CD138, CD38, CD19, cytoplasmic lambda LC. Immunosuppression with triple regimen was adjusted accordingly until PCN was diagnosed. Hemodialysis initiated because of fluid overload and anuric renal failure. After first chemotherapy (Cyclophosphamide, Bortezomib, Dexamethasone), she did have multiorgan failure and expired.

Discussion: Plasmacytoma like PTLD is a rare presentation and have poor prognosis. Prevalence was less than 0.1%. It is reasonable to have systematic screening of light chains in KDIGO recommendations before and after kidney transplantation to prevent the death of patient and graft.

PUB390

Daratumumab Is Effective for the Treatment of Antibody-Mediated Kidney Rejection

Wai-Choong Lye. *Centre for Kidney Diseases, Singapore, Singapore.*

Introduction: ABMR of kidney allografts has been difficult to treat with TPE, IVIG, rituximab and tocilizumab. We present a patient with ABMR that was reversed with the use of SC daratumumab (Dara).

Case Description: A 69-year old man had his first kidney transplant on 2008. He developed chronic ABMR that was unresponsive to rituximab and tocilizumab. He had a second transplant on October 2021. He had no DSA, CDC and flow crossmatches were negative. His discharge serum creatinine was 0.95 mg/dL and biopsy was normal. 16 days post-transplant, he had proteinuria of 4.4 gms/24 hrs, creatinine rose to 1.56 mg/dL, dd-cfDNA (Prospera) was raised at 3.78%. A repeat biopsy showed MVI, g+ptc=4 with +ve C4d staining. MMDx confirmed severe early ABMR. His DSA, anti-AT1-R, MICA antibodies, endothelial cell crossmatch were negative. As he had previously failed rituximab and tocilizumab, he gave informed consent to be treated with SC daratumumab 1800 mg weekly for 4 doses then 3 monthly for 3 doses for a total of 10 months, ending on September 2022. After 4 doses of Dara, his proteinuria decreased to 1.5 gms/24 hrs, creatinine; 1.42 mg/dL, dd-cfDNA decreased to 1.41%. In March 2022, his proteinuria; 1.0 gm/24 hrs, creatinine; 1.36 mg/dL, dd-cfDNA had normalized to 0.14%. His biopsy showed MVI, g+ptc=3, mild C4d staining, MMDx improved to mild early-stage ABMR. In June 2022, his proteinuria; 0.20 gm/24 hrs, creatinine; 1.41 mg/dL, dd-cfDNA was 0.57%. In September 2022, he had no proteinuria, creatinine; 1.45 mg/dL and dd-cfDNA was 0.28%. In January 2023, he had no proteinura, creatinine; 1.32 mg/dL, dd-cfDNA was 0.55%. His biopsy had no ABMR, g+ptc=0, negative C4d staining and MMDx had no ABMR.

Discussion: We report a man with rapid onset ABMR that was successfully reversed with SC Dara over a 10-month period with complete remission in proteinuria, slight decrease in creatinine, progressive improvements in serial dd-cfDNA and resolution of rejection findings on serial biopsies and MMDx. SC Dara was tolerated with minimal side effects. It was conveniently administered as an out-patient over 15 minutes. Dara had been reported to reverse ABMR in a patient who had an ABO-I kidney transplant. Dara had been used to desensitise patients prior to kidney transplant. However, this is the first patient who had an ABMR successfully reversed with SC Dara. We are continuing to enrol more patients with proven ABMR to be treated with SC Dara.

PUB391

Correlation of Urine Analysis Findings with Biopsy-Proven Acute Kidney Transplant Rejection

Mohammad Atari,[1] Bushra Syed,[1] Prathap Simhadri,[2] Pradeep Vaitla,[1] Sanjana Kapoor.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]AdventHealth East Florida, Daytona Beach, FL.*

Background: Although the incidence of acute kidney transplant rejection within the first year has decreased, it remains a major cause of allograft dysfunction. Kidney biopsy remains the gold standard to diagnose rejection. Urine analysis is used in evaluating kidney dysfunction, but no previous studies correlated urine analysis findings with acute rejection.

Methods: We performed a descriptive study evaluating urine analysis findings (proteinuria, hematuria, and pyuria) at the time of biopsy-proven acute rejection in adult kidney transplant recipients. We examined the most recent urine samples before kidney biopsies. We excluded patients with acute rejection who have other histopathological findings that may impact urine analysis findings (advanced diabetic glomerulosclerosis, collapsing glomerulopathy, FSGS, active glomerulonephritis, BK nephropathy, anatomical abnormalities, or concomitant chronic rejection).

Results: Between 2020 and 2023, 44 biopsy-proven acute rejection episodes were diagnosed in 38 patients. Eighteen biopsies showed acute TCMR, ten showed AMR, sixteen showed mixed rejection, and of all the biopsies ten had evidence of vascular rejection. Thirty-six episodes (81.1%) were preceded by abnormal urine analysis. Thirty urine samples (66.6%) tested positive for protein (≥10 mg/dL), thirteen samples (29.5%) tested positive for hematuria (≥3 RBCs/HPF), and eighteen samples (40.9%) tested positive for pyuria (≥3 WBCs/HPF). Of the eight normal samples, 3 were in the setting of AMR, 4 in the setting of TCMR, and 1 in the setting of mixed rejection. Interestingly, mixed rejection was associated with the highest likelihood of having abnormal urine analysis (93.75%).

Conclusions: There is no single urine analysis abnormality that correlates well acute rejection. Although various degree of proteinuria is not uncommon, it is non-specific. Even in the setting of glomerular injury as seen in glomerulitis, hematuria and/or pyuria are inconsistently seen at low rates.

Urine analysis abnormalities in various types of rejection

Rejection subtypes (n)	Urine analysis with abnormalities; n (%)	Protein (≥10 mg/dL); n (%)	RBCs (≥3/HPF); n (%)	WBCS (≥3/HPF); n (%)
Biopsy-proven acute rejection (44)	36 (81.1%)	29 (66%)	13 (29.5%)	18 (40.9%)
Antibody-Mediated Rejection (AMR) (10)	7 (70%)	6 (60%)	2 (20%)	2 (20%)
Acute T-Cell-Mediated Rejection (TCMR) (18)	14 (77.7%)	9 (50%)	5 (27.7%)	9 (50%)
Mixed Rejection (16)	15 (93.75%)	14 (87.50%)	6 (37.50%)	7 (43.70%)
Biopsies with Vascular Rejection (10)	8 (80%)	6 (60%)	3 (30%)	4 (40%)

Skin Lesion Unmasking Disseminated Nocardia in Renal Transplant Recipient

Sarah Abu Kar, Amber Anwar, Laura Binari, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Nocardiosis is a rare opportunistic infection that can cause localized or systemic diseases. Therefore, a high index of suspicion is required for the diagnosis as it carries high mortality if not treated early. We present a disseminated Nocardia infection presenting with an isolated skin lesion.

Case Description: A 47-year-old male suffering from end-stage renal disease due to hypertension underwent a deceased donor kidney transplant in 2/ 2022. He was induced with Alemtuzumab and maintained on tacrolimus, mycophenolate mofetil, and prednisone. He also received prophylactic Dapsone for 6 months (due to a reported sulfonamide allergy) and Valcyte for 4 months post-transplantation. His course was complicated by AMR in 12/ 2022, treated with PLEX, IVIG, and Rituximab. Three months later, he presented with an ulcerated skin nodule on the medial aspect of his right knee. It started after a few days of soil-related teaching activities involving planting and terrarium work. No other symptoms were reported, treated with antibiotics for one week without improvement, so a biopsy and wound culture from the lesion revealed Nocardia pseudobrasiliensis. Subsequent diagnostic workup, including a chest CT scan and an MRI of the brain, uncovered a spiculated lung lesion, a consolidation in the left lower lobe, and two cerebral abscesses. Bronchoscopy with BAL and LP results were negative for malignancy and infection. Additionally, all non-invasive fungal markers were negative. In collaboration with the infectious diseases and pulmonology teams, a diagnosis of disseminated nocardiosis was concluded, aligning with the patient's symptomology. Treatment commenced with linezolid, Bactrim (after consulting with Allergy and tolerating the medication well), and imipenem-cilastatin, which was later adjusted to Bactrim and Linezolid based on sensitivity. Follow-up imaging showed a reduction in the sizes of both the lung nodule and brain abscess, indicating successful treatment progress.

Discussion: Skin lesions can pose diagnostic challenges in transplant patients, necessitating vigilance for atypical presentations of opportunistic infections and proactive biopsy for unresponsive lesions. However, Nocardia, when identified early and treated with targeted antibiotics, can result in successful outcomes for renal transplant recipients.

PUB393

Ultra-Long Survivors of Kidney Transplantation: 40 Years and More of Graft Function

Michelle Madden,[1,2] Gavin Comerford,[1,2] Patrick O'kelly,[1] Anne M. Cooney,[1] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland.*

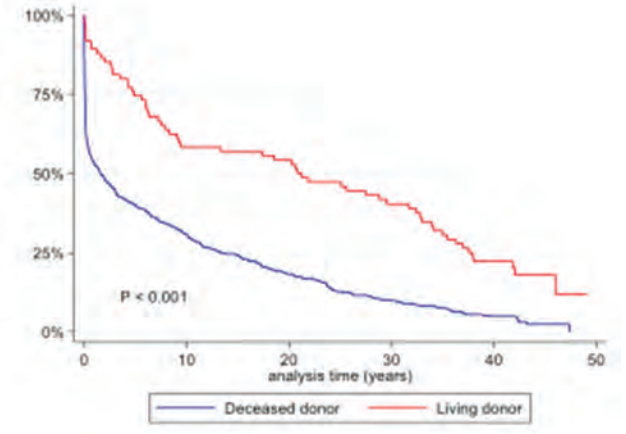
Background: It is nearly sixty years since the first kidney transplant in Ireland in 1964. We examined our cohort of patients with allografts functioning for over forty years. We sought to identify factors associated with this ultra-long-term allograft survival and to describe clinical features of these patients.

Methods: A retrospective analysis of the Irish National Kidney Transplant Registry included all kidney transplants performed in Ireland between 1st January 1970 and 31st March 1983. Follow-up was until 31st March 2023.

Results: 428 transplants occurred in 394 patients. There were 33 (8.4%) patients with graft function for ≥40 years, of whom 25 are functioning at date of analysis. 4 patients were lost to follow-up. Kaplan-Meier estimated survival at 20, 30 & 40 years was 25%, 15% & 8% respectively for all grafts; figure 1 illustrates survival differences between

living and deceased donor grafts. Multivariate analysis identified age at transplant (HR 1.02, CI 1.00–1.04), male recipient (HR 1.39, CI 1.04–1.45) and living vs. deceased donor (HR 0.42, CI 0.27–0.67) as significantly associated with long-term graft loss. The median age at death was 49 years (IQR 40 – 59). The most common causes of death were cardiovascular disease and malignancy. The major causes of graft loss were death with a functioning graft and interstitial fibrosis/tubular atrophy. The median creatinine of 25 surviving grafts was 1.21 mg/dL (range 0.75-3.64 mg/dL). Most (61%) patients were prescribed a combination of azathioprine/glucocorticoid. Comorbidities included non-melanoma skin cancer (67%), coronary artery disease (24%) and invasive malignancy (30%). Skin cancer was by far the commonest malignancy, with 93 incidences in 22 patients.

Conclusions: Of those who survive to forty years, graft function is excellent maintained on low-level immunosuppression. Recipient female sex and living donor kidney transplantation are associated with improved graft survival.



PUB394

Impact of Donation After Circulatory Death on Outcomes of Expanded Criteria Donor Kidney Transplants

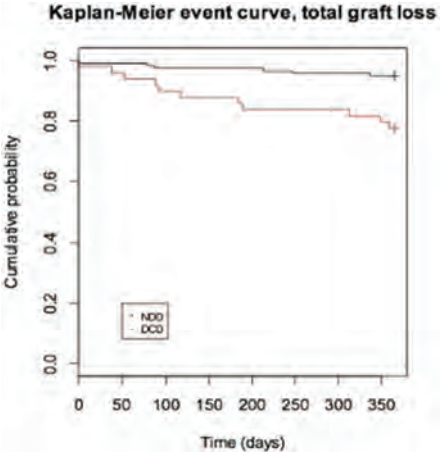
Enad A. Alsolami,[1] Khaled Lotfy,[2] Ahd Alkhunaizi,[2] Meaghan S. Cuerden,[2] Matthew A. Weir,[2] Andrew A. House.[2] *[1]University of Jeddah, Jeddah, Saudi Arabia; [2]Western University, London, ON, Canada.*

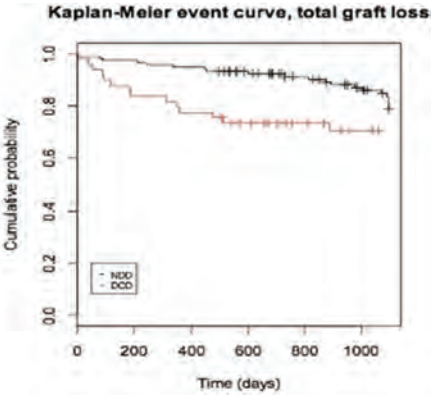
Background: Expanded criteria donor (ECD) kidneys experience suboptimal outcomes compared to standard criteria donor (SCD) kidneys.

Methods: To examine the additional impact of deceased organ category, donation after circulatory death (DCD) and neurological determination of death (NDD), on ECD outcomes, we examined 1- & 3-year patient and graft survival in all ECD kidney recipients in our institution between January 2008 and December 2017.

Results: Of 166 ECD recipients, 49 (29.5%) were DCD and 117 (70.5%) were NDD. Delayed graft function was higher in the DCD/ECD group 61.2 % vs 32.0 % among NDD/ECD recipients. Graft loss was significantly increased among DCD/ECD (HR for graft loss 4.81 (95% CI, 1.78, 13.01), *p* value 0.002 at 1 year and 2.03 (95% CI, 1.03, 4.0), *p* value 0.042 at 3 year). Death-censored graft loss was higher among DCD/ECD (HR was 10.12 (95% CI, 2.14, 47.92), *p* value 0.004 at 1 year and 2.83 (95% CI, 1.24, 6.46) *p* value 0.014 at 3 years). There was no statistically significant difference in all-cause mortality.

Conclusions: Our study demonstrated that DCD/ECD kidneys have lower graft survival compared to NDD/ECD kidneys. Time on dialysis, waiting time and panel reactive antibody should be taken into account when offering these organs to patients.





PUB395

Safety and Efficacy of Mycophenolate Reduction After Kidney Transplantation

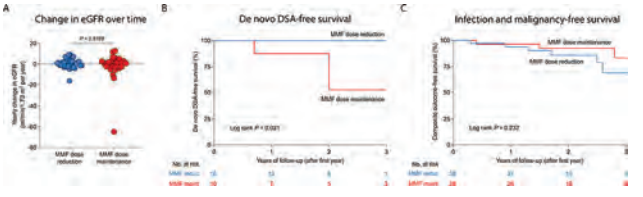
Karim Yatim, Ayman Al Jurdi, Guilherme Taborda Ribas, Leela Morena, Leonardo V. Riella. *Massachusetts General Hospital, Boston, MA.*

Background: Adjusting the dose of maintenance immunosuppression (IS) after kidney transplantation is essential to balance the risk of allograft rejection with that of infections and malignancy. Contrary to tacrolimus, there are no high-quality data to guide mycophenolate (MMF) dose changes in kidney transplant recipients (KTRs). The aim of this study is to determine the allograft and patient outcomes in KTRs who underwent MMF dose reductions compared to those who did not at our institution.

Methods: We conducted a retrospective cohort study of all kidney transplants from 1/1/2015 to 12/31/2020 who received MMF-based IS. The "intervention" group included KTRs who underwent MMF dose reduction after the first year, while the control group was KTRs whose MMF dose was maintained. The primary safety outcomes were graft failure or death, de novo DSA development, allograft rejection, and eGFR change during follow-up. The primary efficacy outcome was a composite of new viral infections (CMV, EBV and BKV), infections requiring hospitalization and malignancy. We excluded patients who developed infections or malignancy prior to MMF reduction from our analysis. Follow-up was censored at occurrence of the outcome, last follow-up or five years.

Results: 69 KTRs met the inclusion criteria. Mean age was 49.5±15.3 years, 61% were male (n=42), 59% received a deceased donor allograft (n=41), and 86% (n=59) received Thymoglobulin. 42 KTRs (61%) had a reduction in the MMF dose after 1 year of transplantation to ≤500 mg BID. No deaths occurred during follow-up. 3 (4%) KTRs developed rejection during follow-up: 1 mixed acute rejection in the MMF dose maintenance group, and 2 cellular rejections in MMF dose reduction group. There was no change in eGFR between groups (Figure 1A). DSA occurred in 3 KTRs (4%), all in the MMF dose maintenance group (Figure 1B). There was no difference in the incidence of composite outcome of infections and malignancy (Figure 1C).

Conclusions: MMF dose reduction after the first year may be a safe strategy in low-risk KTRs. Larger prospective studies are needed to confirm these findings and establish the long-term benefits of this intervention regarding infection and malignancy.



PUB396

Tacrolimus Intrapatient Variability as a Tool to Gauge Nonadherence in Adolescent Kidney Transplant Recipients

Tara B. Gavcovich,[1,2] Vaka Sigurjonsdottir,[1,2] Marissa J. Defreitas,[1,2] Claudia Serrano,[1,2] Wacharee Seeherunvong,[1,2] Chryso P. Katsoufis,[1,2] Wendy R. Glaberson,[1,2] Melisa Oliva,[1,2] Adela D. Mattiazzi,[1,2] Carolyn L. Abitbol,[1,2] Jayanthi Chandar.[1,2] *[1]Jackson Memorial Hospital, Miami, FL; [2]University of Miami School of Medicine, Miami, FL.*

Background: Long-term survival of kidney allografts is limited by rejection, a common cause of graft loss in adolescent transplant recipients. High tacrolimus intrapatient variability (IPV) has been associated with DSA formation and increased risk of rejection. Non-adherence is considered a cause of high tacrolimus IPV, but has not been demonstrated conclusively.

Methods: This cross-sectional retrospective study included kidney-only transplant recipients ≥11 to ≤23 years old, ≥10 months post-transplant at the Miami Transplant Institute, and maintained on tacrolimus. A composite adherence score ranging from 0-4 points was developed using four tools, each awarded 1 point if positive: (1) patient reported non-adherence on Basel Assessment of Adherence to Immunosuppressive Medical Scale (BAASIS©); (2) provider report; (3) inability to recall medications; and (4) intentional missed visits. A composite score ≥1 was considered non-adherent. Tacrolimus levels were monitored at least monthly. IPV is the coefficient of variation: SD/mean tacrolimus concentration x 100%, using tacrolimus samples in the 6 months prior to adherence assessment. Levels drawn while hospitalized/sickness or mis-timed levels were excluded.

Results: 33 patients were enrolled, 60.6% male, median age 16 years (IQR 13-19). Non-adherence was noted in 18 (54.5%) patients. The median tacrolimus IPV was significantly higher in non-adherent (32%, IQR 14-37.5) compared to adherent patients (18%, IQR 13-22), p=0.02 (Figure 1a). There was a significant positive correlation between tacrolimus IPV and BAASIS© score (r= 0.45, 95% CI 0.13 - 0.69), p<0.01 and composite adherence score (r= 0.56, 95% CI 0.26 - 0.76), p<0.001 (Figure 1b).

Conclusions: Tacrolimus IPV was significantly higher in non-adherent patients. Recognizing high IPV may be a useful tool to detect non-adherence in adolescent kidney transplant recipients at high risk of rejection, allowing for early interventions to prevent adverse graft outcomes.

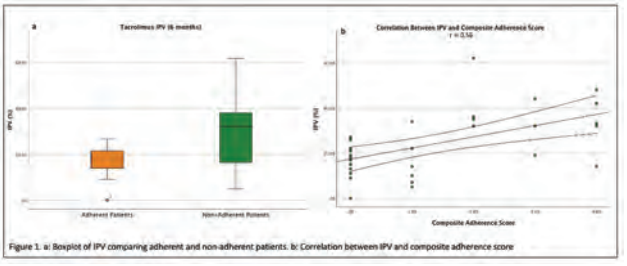


Figure 1. a) Boxplot of IPV comparing adherent and non-adherent patients. b) Correlation between IPV and composite adherence score

PUB397

Disseminated Intravascular Coagulation in the Immediate Postoperative Period After a Simultaneous Kidney Pancreas Transplant (SPK)

Mohammed A. Sayeed Khan, Tanu Duggal, Aadil Kaisani. *Baylor Scott and White Central Texas, Temple, TX.*

Introduction: Disseminated intravascular coagulation(DIC) is a clinico- pathological syndrome associated with consumptive coagulopathy and defibrination with a potential of causing micro/macrovascular thromboses and hemorrhage. DIC is commonly caused by inflammation, drugs, sepsis, severe trauma or major surgery, cancer, obstetric complications, immune reactions. While there are multiple cases of DIC in deceased donors, there is no data or case reports on recipients developing DIC immediately post-op after SPK.

Case Description: 59-year-old female underwent a SPK for a history of ESRD secondary to IDDM2. Measured PRA was 61%/43%. DBD Donor -18 year old female who died from Anoxia. KDPI - 9% and P-PASS <17. No DSA noted and was a 2/6 HLA ABDR Match. CIT- was less than 15 hours for both organs. Intraoperative course was unremarkable. Within 4 hrs she became obtunded and hypotensive progressing to multipressor shock. Labs showed a drop in hemoglobin-9.7g/dl to 6.5g/dl(N 12-16), platelets-239 to 84 10*9/L (N 150-450 10*9/L). She was emergently taken back for rexploration. There was no anastomotic leak, only nonspecific diffuse oozing into the abdomen. Both grafts were healthy and no signs of hyperacute rejection. Her coagulation parameters deteriorated-PT-12.3 to 30.1(N 9-12 seconds), aPTT- 33.1 to 65.9 (N 25-36 seconds), INR- 1.1 to 2.5(N 0.9-1.1), D-dimer-14.90 and fibrinogen 135. International Society on Thrombosis and Hemostasis criteria met for overt DIC. She was treated with blood products per protocol, CT scan showed extensive Hepatic and splenic infarcts in addition she developed purpura fulminans and multi-organ failure. Final diagnosis-Hemorrhagic shock due to DIC.

Discussion: SPK has evolved as the gold standard treatment for patients with ESRD with IDDM2 in surgically acceptable candidates. it is a more complex procedure with a higher complication rate. Rexploration is seen in >20% with the most common etiology being anastamotic leaks, intraabdominal fluid collections, Intrabdominal infections, graft pancreatitis and graft thrombosis. Cases of DIC have been reported after surgical interventionsm but to our knowledge there is no documented case of rapid onset DIC in a patient post SPK. This case highlights the need to consider DIC in a postoperative setting after DIC in patients with hemorrhagic shock which has previously not been reported.

PUB398

To Bleed or to Thrombose: The Potential Risks and Complications of Blood Thinners in Kidney Transplant Recipients

Anam Rehan,[1] Grace Qiu,[1] Prashamsa Shenoy,[1] Rachel Greene,[1] Goni Katz-Greenberg,[2] Maria P. Martinez Cantarin.[1] *[1]Thomas Jefferson University, Philadelphia, PA; [2]Duke University, Durham, NC.*

Background: Many patients on the kidney transplant waitlist are on anticoagulation (AC) or antiplatelet therapy for various indications and co-morbidities. These medications are associated with increased risk of bleeding, especially when patients undergo invasive procedures, such as a kidney transplant. On the other hand, withholding AC or antiplatelet therapy in the perioperative period, can lead to complications such as vascular thrombosis and subsequent allograft loss. The aim of our study was to review co-morbidities and allograft function of kidney transplant recipients (KTRs) on these medications at the time of transplant.

Methods: Single center, retrospective cohort study of adult KTRs transplanted between Jan 2017 and December 2019 in our center.

Results: We had 333 KTRs who met the study criteria. Of them, 38.9% of were on Aspirin pre-txp, 5.4% were on Plavix and 8.4% were on Coumadin as anticoagulation. Of the 333 KTRs, 22 patients (6.6%) developed a hematoma and 8 patients (2.4%) developed thrombosis. Usage of pre-operative AC or antiplatelet therapy did not differ between KTRs who developed these complications and those who did not. Compared to KTRs who did not develop a hematoma post-KT, patients with hematomas had longer length of stay (LOS)(p<0.001), higher intervention rate in the OR (54.5% vs 5.5%, p<0.001) or by CVIR (45.5% vs 13.9%, p=0.001) within 30 days post-KT. KTRs with hematoma also had higher serum creatinine (Cr) at 30 days (p=0.003), 90 days (p=0.001), 1 year (p= 0.001) and at the latest follow up (p<0.001). Overall patient survival was also significantly lower in this group (p<0.05). KTRs with thrombosis had longer LOS (p<0.001) and higher Cr after 30 days (p<0.05) when compared to those without. KTRs with thrombosis had lower graft survival (p=0.05).

Conclusions: Bleeding or thrombosis complications post-transplant are associated with significant morbidity but they did not occur more frequently in patients that were on AC or antiplatelet therapy pre-transplant. While this is a single-center study, it contributes to existing data, and highlights the fact that the risks and benefits of AC therapy should be assessed for each patient to individualize the management approach.

PUB399

Risk Factors for Fractures in Renal Transplantation: A Population-Based Cohort Study

Jei-Wen Chang,[1,2] Tzu-Ching Lin,[1,2] Hsin-Lin Tsai.[1,2] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Background: Kidney transplant recipients are at an increased risk of fractures, and targeted preventive strategies are needed. Therefore, we investigated a large population-based cohort to identify the transplant recipient-specific risk factors for fractures in Taiwanese kidney transplant recipients.

Methods: We conducted a retrospective cohort study using the National Health Insurance Research Database. Patients who underwent renal transplantation between 2003 and 2015 were identified and followed until December 31, 2015 to observe the development of fractures. Variables associated with the development of post-transplant fractures were identified by calculating hazard ratios in a Cox regression model.

Results: 5309 renal transplant recipients were identified, of whom 553 (10.4%) were diagnosed with post-transplant fractures. Independent predictors of post-transplant fractures included an age at transplant ≥65 years (p<0.001), female sex (p<0.001), fractures within 3 years prior to transplantation (p<0.001), and diabetes (p<0.001). In addition, daily prednisolone dose >2.9-5.3 mg/day (p<0.001), >5.3-8.7 mg/day (p<0.001) and >8.7 mg/day (p<0.001) were also independent predictors of post-transplant fractures. Conversely, the use of peritoneal dialysis before renal transplantation (p=0.021), hypertension (p=0.005), and the use of tacrolimus (p<0.001), azathioprine (p=0.006), mycophenolate mofetil (p=0.002), mTOR inhibitors (p=0.004) and calcium supplements (p=0.009) were inversely correlated with post-transplant fractures.

Conclusions: We recommend minimizing daily glucocorticoids in conjunction with immunosuppressive regimens such as tacrolimus, azathioprine, mycophenolate mofetil, mTOR inhibitors and calcium supplements, especially in older female recipients, and in recipients with diabetes and a history of prior fractures.

Funding: Other U.S. Government Support, Government Support - Non-U.S.

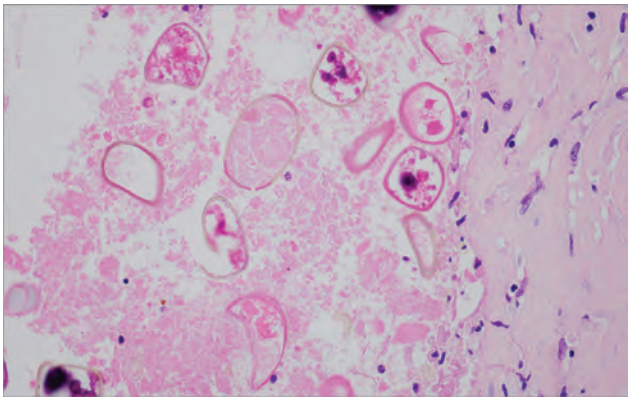
Paragonimiasis Mimicking Ureter Stone in Living Kidney Donor

Hae Sang Park,[1] Young-Joo Kwon.[2] [1]*H Plus Yangji Hospital, Seoul, Republic of Korea;* [2]*Korea University Guro Hospital, Seoul, Republic of Korea.*

Introduction: Extrapulmonary paragonimiasis mainly involve pleural, subcutaneous, cerebral, and spinal infection. Other extrapulmonary paragonimiasis has been reported in hepatic, splenic, abdominal, urinary, and gynecologic organs. We report a case of paragonimiasis mimicking ureter stone in living kidney donor.

Case Description: We decided kidney transplantation between the married couple. The living donor was 61 year old male, and his CT angio abdomen scan showed about 0.6 cm stone at left proximal ureter, and small size periureteral low density lesion at the left proximal ureter. In operation, we found of a lump of soft tissue in periureter, measuring 4.5x4x2.5cm, yellowish adipose tissue-like appearance. Frozen specimen cut surface showed cystic appearance filled with yellowish necrosis like material, and was diagnosed as parasite infection, morphologically paragonimiasis. Kidney transplantation was done steadily, and post-operative course progressed smoothly.

Discussion: Donor showed positive in P.westermani Ab and Cysticercus Ab, but recipent showed negative. After further interview, he had history of paragonimiasis and taking praziquantel 15 years ago. We prescribed to her praziquantel 1,800 mg for 3 days. In post transplant three month, her serum creatinine incresed from 0.95 mg/dL to 1.57 mg/dL, and sonogram showed hydronephrosis. We decided double J stent insertion through percutaneous nephrostomy, and follwed up for eight months cautiously. Even though waiting, proximal ureter stricture was incurred, and she has been regular double J stent exchange under general anesthesia. Even if extraplumonary paragonimiasis involving ureter is very uncommon, the meticulous history taking and examination would be needed in transplantation work up.



Parasite infection, Morphologically paragonimiasis

Clinical Course of a Kidney Transplant Recipient with Epstein-Barr Virus Viremia Treated with Maribavir

Sapna Shah, Thin Thin Maw, Santhi Voora. *University of Southern California, Los Angeles, CA.*

Introduction: Impaired T-cell immunity following kidney transplantation increases the risk of both primary infection and reactivation of latent Epstein-Barr Virus (EBV). EBV viremia is managed primarily with reduction in maintenance immunosuppression, but with varied results. We present the first clinical case of a kidney transplant (KT) recipient with EBV viremia treated with Maribavir, a novel therapeutic that inhibits EBV transcription and viral replication.

Case Description: A 70-year-old Taiwanese female with a history of end stage kidney disease secondary to diabetic nephropathy underwent a deceased donor KT with thymoglobulin induction. She received maintenance immunosuppression with tacrolimus, mycophenolate, and prednisone. At the time of transplantation, she was at moderate risk for EBV infection with both donor and recipient EBV IgG antibodies positive (recipient IgG 526 Unit/mL; IgM <10 Unit/mL). Six months later she had worsening leukopenia and was diagnosed with EBV viremia that initially resolved with reduction of mycophenolate. Sixteen months following KT she again developed EBV viremia. She had persistent and worsening viremia despite cessation of mycophenolate, dose reduction of tacrolimus, and Prednisone to 2.5 mg daily. She was initiated on IV immunoglobulin 500 mg/kg, but treatment was discontinued after her first dose due to the development of severe myalgia, transaminitis, and hemolytic anemia. She was then initiated on off-label Maribavir 200mg twice daily with significant improvement in viremia. Figure 1 summarizes her treatment course.

Discussion: Maribavir is a novel benzimidazole riboside compound that inhibits EBV DNA polymerase processivity factor (BMRF-1), reduces some EBV glycoproteins, and inhibits EBV viral transcription. Maribavir treatment was well tolerated at 200mg twice daily. Maribavir is the only intervention that was associated with a significant reduction in EBV viremia in this patient.

The Molecular Microscope Diagnostics System (MMDx) May Have the Potential to Differentiate Molecular T Cell-Mediated Rejection (TCMR) Among Kidney Transplant Recipients with Chronic-Active TCMR

Thomas Schachtner, Lukas Weidmann, Dusan Harmacek, Kai C. López, Raphael Korach, Nicola Bortel, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: Treatment of chronic-active T-cell mediated rejection (caTCMR) lacks consensus, causing many different therapeutic approaches. If changes in transcript patterns analyzed by the Molecular Microscope Diagnostic System (MMDx) may differentiate among these cases with caTCMR and offer additional diagnostic value needs to be evaluated.

Methods: In this single-center cohort of 326 indication kidney transplant biopsies assessed by histology and MMDx at the University Hospital Zurich, we analyzed 15 cases with caTCMR after the exclusion of overlapping pathologies such as BK nephropathy, pyelonephritis, and acute interstitial nephritis. 7 cases with combined acute TCMR and caTCMR were compared to 8 cases with caTCMR only.

Results: 3 of 7 cases (43%) with combined acute TCMR and caTCMR, and 1 of 8 cases (13%) with caTCMR only showed pure molecular TCMR. In addition, 3 of 7 cases (43%) with combined acute TCMR and caTCMR, and 4 of 8 cases (50%) with caTCMR only showed mixed molecular ABMR/TCMR with histologic ABMR in 5 of 7 cases (71%). Among 3 of 8 cases (38%) with caTCMR only but no molecular rejection, 2 cases showed an all ABMR rejection phenotype score (sum of R4, R5, and R6) ≥0.20, and 1 case showed a TCMR phenotype score (R2) ≥0.10.

Conclusions: The MMDx may have the potential to differentiate histologic caTCMR into molecular TCMR, molecular ABMR/TCMR, or no molecular rejection. Whether the observed minor molecular findings are attributable to undetected overlapping pathologies, cortex/medulla sampling variations, or a suspected continuum of caTCMR needs to be studied.

PUB403

Five Scenarios Across the Antibody-Mediated Rejection (ABMR) Continuum: The Added Value of the Molecular Microscope Diagnostic System (MMDx) Confirmed by Follow-Up Biopsies

Thomas Schachtner, Kai C. López, Lukas Weidmann, Dusan Harmacek, Nicola Bortel, Raphael Korach, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: The Molecular Microscope Diagnostic System (MMDx) has evolved to be an essential tool in suspected antibody-mediated rejection (ABMR). However, cost and availability limit a generalized use making it even more important to outline specific scenarios in which MMDx may add significant diagnostic value.

Methods: In this single-center cohort we analyzed 22 kidney allograft biopsies, including 9 follow-up biopsies assessed by histology and MMDx.

Results: "Isolated glomerulitis": Two cases w/o DSA showed isolated glomerulitis (g1, ptc0, v0). On a follow-up biopsy one year later, histology no longer demonstrated glomerulitis, and MMDx confirmed no rejection in each biopsy. "MVI in the absence of DSA": Two cases showed MVI (g+ptc≥2) in the absence of DSA. On follow-up biopsy, histology showed ongoing MVI in one case, confirmed by MMDx in each biopsy. On follow-up biopsy in the second case, histology showed no MVI (g0, ptc0), and MMDx confirmed no ABMR in each biopsy. "MVI in ABOi transplantation": Two cases after ABOi transplantation were diagnosed with TCMR plus MVI in the absence of DSA, confirmed by MMDx with molecular TCMR. After successful treatment of TCMR, MVI persisted on follow-up biopsy without any clinical suspicion for ABMR. MMDx showed no ABMR in each biopsy. "Mixed rejection": In two cases with malcompliance, ABMR could not be diagnosed according to Banff with concomitant TCMR, but MMDx suggested ABMR/TCMR in both cases. After treatment for ABMR/TCMR, one case showed ongoing ABMR by histology and MMDx, while the other case showed resolved ABMR by histology and MMDx. "Early active ABMR": One case showed no rejection on histology one week post-transplant but minor ABMR by MMDx. On follow-up biopsy two weeks later, ABMR was confirmed by histology and MMDx. Four other cases with early active ABMR within the first two post-transplant weeks showed ABMR by histology and MMDx.

Conclusions: The MMDx appears to have added value across the ABMR continuum, both to confirm and reject the diagnosis of ABMR. In addition to the Banff 2019 recommendation, scenarios such as MVI in ABOi transplantation and mixed rejection should be considered as indications for the MMDx. Earlier diagnosis of early active ABMR, while possible with MMDx, is likely the exception.

First Year After Transplant Infections in a Young Kidney Transplant Cohort: Is Preemptive Transplant Protective?

Lamis E. Khedr. Kidney Transplant Center Ain Shams Specilaized Hospital. *Ain Shams University Faculty of Medicine, Cairo, Egypt.*

Background: Infection after a kidney transplant is a serious cause of morbidity and mortality. Weighing the risks and benefits of immunosuppression is of paramount importance to patient wellbeing and transplant survival.

Methods: This is a prospective observational study looking at the variety of infections in a young cohort with living related kidney transplant. Fifty-one records of patients who had a kidney transplant between Jan 2020 and Jan 2022 were followed up and clinically significant infections were investigated and documented.

Results: This was a young transplant cohort with a mean age of 28.4 ± 10.4 yrs. Females were 45.1%. The commonest infection was lower urinary tract infection *(UTI)* (27.3%) followed by SARS-COV2 and Herpes Zoster (15.2%). Median Tacrolimus level was (7.8) ng/ml and was slightly higher in the group without infection (8.95) ng/ml P=0.21. Haemoglobin was higher in the group without infection median (10.8) gm/dl (7.3-15.3) compared to (10.2) gm/dl in the group without infection (7.8-14) odds ratio *(OR)* = 0.78 confidence interval *(CI)* (0.5-1.1). More infections were recorded in Kidney transplant recipients *(KTR)* from donors over the age of 60 (0R =2.6 ;95% CI :0.5-12; P=0.2). Post transplant diabetes *(PTDM)* was more prevalent in the group with infection (25%) (OR 1.9 p =0.365). In the group without infection, 59.3% had a preemptive transplant compared to 20.8% in the group with infection (OR= 0.18; 95% CI: 0.052-0.631; P=0.007).

Conclusions: This study shows that the distribution of infection in this cohort with living related kidney transplantation. Lower urinary tract infection was the commonest infection followed by SARS-COV2 and Herpes Zoster. We observed a lower incidence of infection with preemptive transplantation.

Quality Improvement Initiative to Enhance Post-Renal Allograft Biopsy Follow-Up

Mingyue He,[1] Jean Lee,[2] Sheetal Koul,[2] Iris J. Lee,[2] Avrum Gillespie.[2]
[1]Temple University Hospital, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.

Background: Kidney transplant recipients who undergo allograft biopsies are often discharged on the same day with instructions to schedule a subsequent visit with Transplant Clinic for results and further management plans. Such patient-initiated follow-ups can lead to care delays and patient dissatisfaction. Furthermore, inadequate documentation of communication with patients regarding biopsy results can contribute to confusion among physicians. We thus implemented patient-centered interventions to improve 30-day follow-up and identify potential late-onset complications of kidney allograft biopsy. These interventions include concurrent scheduling of biopsy and post-biopsy follow-up visits, reminding patients of their appointment on the day of the biopsy, post-procedure phone check-ins, and improved documentation of biopsy result communications.

Methods: We analyzed a pre-intervention sample of 23 renal allograft biopsies from January to April 2021. Post-intervention, we reviewed all 24 renal allograft biopsies performed from January to April 2022. We compared the rates of 30-day follow-ups, either through telehealth or in-person visits with documented biopsy result discussions, over a four-month period before and after the intervention.

Results: No significant differences were observed in baseline clinical characteristics between pre-and post-intervention groups: Age: 53 ± 2.7 vs 48 ±2.9 years, p=0.11; Male: 65.2% vs 45.8%, p=0.18. The 30-day follow-up rate was 87.0% (20/23) pre-implementation and 100% (24/24) post-implementation, (p=0.07). The average interval between biopsy and follow-up date shortened from 18 ± 3.6 days pre-intervention to 12 ± 1.5 days post-intervention (p=0.07). The rate of major treatment modification during follow-up visits was 52.2% before the intervention and 66.7% after it (p=0.31).

Conclusions: The implementation of these patient-centered interventions led to an improvement in post-renal allograft biopsy follow-up rates, although not statistically significant with a borderline p-value. The limited study power due to small sample size may have contributed to this outcome. We observed that over 50% of transplant recipients require treatment modifications post-biopsy, emphasizing the need for prompt follow-up. Hence, further studies exploring ways to improve follow-up efficacy are warranted.

PUB406

Missed Diagnosis as Risk Factor for Graft Loss: Analysis of the Tuscany Kidney Transplant Waitlist

Giuseppe L. Spatoliatore, Giuseppina Rosso, Luca Malatesta, Micaela Anna Casiraghi, Giulia Sossai, Fiammetta Ravaglia, Alberto Rosati. *Azienda USL Toscana Centro, Firenze, Italy.*

Background: A significant percentage of patients on the kidney transplant waitlist have no primary diagnosis. Nonetheless, recurrence of glomerulonephritis (GN) is the second leading cause of graft loss and the majority of patients with unknown etiology of ESKD (uESKD) are frequently labelled as "presumed GN". Furthermore, the burden of inherited kidney diseases in uESKD population is actually uncertain. By far, it is not known whether the lack of primary diagnosis represents a risk factor for graft loss.

Methods: A total number of 537 patients placed on the transplant waitlist in Tuscany were examined retrospectively up to April 2023. We evaluated, by univariate and multivariate analysis, if the lack of diagnosis was a risk factor for graft failure in patients waiting for their first or further transplant.

Results: Out of 537 patients listed in the Tuscany area, 43.5% had missed diagnosis. The distribution by gender, age and comorbidities were comparable between patients waiting for their first or further transplant. In our cohort, 32.6% of patients were waiting for re-transplant, among them 45.4% with uESKD, mostly represented by presumed GN (66.6%). In multivariate analysis, both primary GN (p<0.013, CI: 0.176-0.815) and presumed GN prior to transplant (p<0.043, CI: 0.222-0.978) proved to be a risk factor for graft loss.

Conclusions: A significant percentage of patients placed on the kidney transplant waitlist presents an uESKD, which embraces presumed GN and inherited kidney diseases. Besides primary GN, presumed GN prior to transplant appears to be a risk factor for graft loss but, unlike in primary GN, a targeted therapeutic approach is not feasible. Our study has some limitations, such as possible confounding factors/selection bias in listing ESKD patients. Additional analysis are needed to confirm these findings. Meanwhile we have been implementing a regional program to reduce the percentage of uESKD of both immune-mediated and inherited kidney diseases. A multidisciplinary team has developed a specific algorithm based on AI-related tools, to help guiding the diagnostic process by genetic evaluations, more extensive use of biopsy and proteomic-related analytical techniques.

PUB407

Therapeutic Plasma Exchange with TPE 2000 Membrane for Antibody-Mediated Cardiac Transplant Rejection

Paola Borbolla, Allan Mendez Rodriguez, Eduardo Herrera, Lilia M. Rizo Topete. *Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico.*

Introduction: The removal of pathogenic substances by therapeutic plasma exchange (TPE), as a treatment for antibody-mediated rejection (AMR) in cardiac transplant, has gain a way as a modern medical therapy. Membrane filtration with TPE 2000 (Fig. 1), targets large-molecular-weight substances present in plasma as immunoglobulin. TPE could be offered as initial therapeutic intervention as it rapidly removes antibodies and cytokines from patients' plasma with a technology already in ICU: CRRT machines.

Case Description: A 24-year-old woman, post cardiac transplantation 4 months prior, arrived to ER with dyspnea, orthopnea and oliguria. BP 91/64 mmHg, HR 120bpm, 24 RR, O2 sat 85%. Echocardiography: LVEF 20%, severe cardiac graft dysfunction. A myocardial biopsy was performed. She presented pulseless electrical activity and ALS were performed for 2 minutes with success. Inotropic and vasopressors were started, orotracheal intubation was required. Biopsy shows changes compatible with AMR. Steroids and TPE were offered. 5 sessions with TPE 2000 membrane, prescription with 1.5L plasma exchange with albumin at 25% (Table 1). Vasopressor reduction, inotropic withdrawal, and LVEF increase to 40% were achieve after treatment.

Discussion: Allograft dysfunction due to AMR is one of the worst complications post heart transplantations. In this case we were able to evaluate allograft improvement. LVEF pre-TPE 20% to post-TPE 40%. This can guide us to continue the research about TPE in AMR as there is no evidence-based guidelines that establish this therapy for patients as complex as this are.

Evolution of Kidney Function Following Living Donor Nephrectomy

Ana C. Acosta Peña, Jose H. Cano Cervantes, Mayra M. Matias Carmona, Beatriz R. Cerezo Samperio. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: The Glomerular filtration rate (GFR) pre and post renal donation can vary according to the population and lifestyle, so there is a long -term risk of developing renal disease, so the long -term follow -up is of the utmost importance.

Methods: Retrospective, descriptive and analytical study of donors registered at the National Medical Center "20 de Noviembre" from May 2016 to August 2021 with 1 year follow -up. The objective is to determine the evolution of renal function per year in renal organ donors.

Results: We find 23 women (51%) and 22 men (49%) whose basal characteristics were: age 41 years, serum creatinine (Crs) of 0.76 mg/dl, eGFR CKD-EPI 108 ml/min/1.73m2; Creatinine clearance (CrCl) 106 ml/min; and GFR with DTPA 126 ml/min. A significant difference was found at one year of evolution between the pre and post-donation values of: Crs (Dif. = 0.35 mg/dl; p <0.0001); eGFR CKD-EPI (Dif. = 32.3 ml/min/1.73m2; p <0.0001); and CrCl (Dif. = 36.4 ml/min; p <0.0001). Also there is a difference between Crs values between women and men (0.94 vs 1.3 mg/dl; p <0.0001, 95% IC 0.46 - 0.24) and CrCl (56.5 vs. 71.3 ml/min; p = 0.005, 95% IC 24.8 24.8 - 4.6). There was no significant difference between pre- and post-donation albuminuria (p = 0.06) with an average of 24.3 mg/day (± 86.9 mg/day), no difference between genres (p = 0.51).

Conclusions: The decrease in the glomerular filtration rate and creatinine clearance in our population was on average of 32 to 36 ml/min, without finding an association between the body mass index and the development of hypertension to this, however, with a trend associated with the age of donation.

Comparison of the renal function basal vs post nephrectomy

Variable	Basal	One year post nephrectomy	Results
Creatinine mg/dl	0.76 (± 0.16)	1.1 (± 0.25)	Dif= 0.35 p<0.0001 CI 95% 0.32-0.39
eGFR CKD EPI ml/min/1.73m2	108 (± 16.4)	76 (± 17.4)	Dif= 32.3 p<0.0001 CI 95% 35.4-29.2
eGFR MDRD ml/min/1.73m2	102.3 (± 19.9)	65.4 (± 14.9)	Dif= 36.9 p<0.0001 CI 95% 33.6-40.1
CrCl ml/min	106 (± 24)	63.9 (± 15.2)	Dif= 36.4 p<0.0001 CI 95% 47-25.9

Heart Failure with Reduced Ejection Fraction (HFrEF): Contraindication to Kidney Transplant?

Alice H. Won, Ashwin Kelkar, Gabriel J. Stryjniak, Maria Karas, Darshana M. Dadhania. New York Presbyterian-Weill Cornell Medicine. *Weill Cornell Medicine, New York, NY.*

Background: Heart failure is frequent complication of advanced CKD and many transplant candidates will have reduced ejection fraction (EF). Data remains limited on whether heart failure with reduced EF (HFrEF) at the time of transplant is associated with an increased risk of graft failure and mortality. In this study, we sought to compare the patient and graft survival between the cohorts of patients with or without HFrEF undergoing renal transplantation.

Methods: We performed a retrospective matched cohort analysis of 32 patients with pre-transplant EF </=45% (HF cohort) and 67 patients with EF >45% (control cohort) based on transthoracic echocardiogram, transplanted between January 25, 2011 and July 21, 2015. Patients without pre-transplant EF were excluded from the analysis.

Results: Baseline characteristics were similar except ATG induction was less frequent in the HF cohort (Table1). At a median of 86 months post-transplant, no statistically significant difference was observed between the control and HF cohorts on the overall graft survival (Figure 1, p=0.29) and the overall patient survival (Figure 2, p=0.53). There was no statistically significant difference in the mean creatinine levels at 1 year post-transplant between the control (1.41 mg/dL) and HF (1.48 mg/dL) cohorts, as well as in the hospitalization rates within 1 year of transplant.

Conclusions: In this pilot study, we examined the graft and patient survival outcomes of renal transplant patients with heart failure and found no significant differences compared to matched controls. Our data suggests that ESKD patients with low EF prior to transplant may have significant improvement in their heart function post-transplantation. Low EF alone should not be a contraindication to kidney transplant.

Table 1. Study Cohort

Patient Baseline Characteristics	HF cohort (n=32)	Control cohort (n=67)	p value

Effectiveness of Evusheld (Tixagevimab/Cilgavimab) in Reducing Breakthrough COVID-19 Infections Among Vaccinated Kidney Transplant Recipients

Arezou Shahmoradi, Wilma M. Hopman, Jessy Donelle, Gail Dean, David C. Holland, M. Khaled Shamseddin. *Queen's University, Kingston, ON, Canada.*

Background: Transplant patients are at high risk of COVID-19 infection and its complications. Up to 33% of transplant patients have inappropriate response to COVID-19 vaccination with 2% mortality risk. Studies showed significant reduction with breakthrough COVID-19 infection post Evusheld administration. An Evusheld Clinic was launched at our center, in late July 2022, to facilitate the Evusheld administration to our kidney transplant patients. The aim of this study was to evaluate the efficacy of Evusheld pre-exposure prophylaxis preventing breakthrough COVID-19 infection among vaccinated kidney transplant patients in a single center study.

Methods: We conducted a retrospective analysis of all kidney transplant patients at our center with breakthrough COVID-19 infection post-Evusheld administration between August 1, 2022 and January 6, 2023. Chi square and Fisher Exact test were performed using SPSS Statistics 23 with a 0.05 significance value.

Results: 217 patients were included (Male: 66.8%; Age: 56.9±14.2years). 127 (58.5%) patients received Evusheld 300 mg through our clinic between August 1 - November 30, 2022. By January 6, 2023, 27 (12.4%) patients developed breakthrough infection since August 1, 2022, compared with a total of 76 (35.9%) COVID-19 infections since the pandemic in March 2020. 19 (15%) breakthrough infections were reported post-Evusheld administration compared with 8 (9%) cases in patients who did not receive Evusheld (*P*=0.18). All Evusheld patients with breakthrough infections were fully vaccinated (3 vaccine doses) compared with 75% of those with no Evusheld and breakthrough infections (*P*=0.08). Time from the last COVID-19 vaccination to infection was not significantly different among patients with and without Evusheld [4.6 (0.5-8.8) vs. 6.5 (92-8-10.6); *P*=0.46].

Conclusions: Evusheld 300 mg did not decrease the risk of breakthrough COVID-19 infection among fully vaccinated kidney transplant patients. Studies with higher doses of Evusheld and further COVID-19 vaccination are still required to determine efficacy of prevention of breakthrough COVID-19 infection among transplant patients.

PUB411

Analyzing the Influence of Demographic Factors on Kidney Transplantation Willingness Among Central Virginia Kidney Disease Patients

Ohm S. Tripathi,[1] Ambreen Azhar,[2] Gaurav Gupta.[2] [1]*University of Connecticut, Storrs, CT;* [2]*Virginia Commonwealth University Health System, Richmond, VA.*

Background: Kidney transplantation (KT) offers increased quality of life and improved clinical outcomes (including patient survival) as compared to dialysis treatment. Barriers in access to earlier steps of transplantation (i.e. referral and evaluation)

are inadequately reported in the current research field. The study aimed to identify educational barriers, racial barriers, socioeconomic-based barriers, and culture-based barriers. Resources seeking to develop educational interventions for both patients and providers may aid in reducing existing barriers.

Methods: A survey consisting of fourteen total questions was administered to patients of varying stages of kidney disease at the Prince George, Southside, and Midlothian Clinic locations in Central Virginia. The study sought to evaluate the role of race and education level on familiarity of kidney transplantation/donation, comfortability with KT, and trust in health care systems.

Results: 103 patients across the three Central Virginia clinics were surveyed between late-March to mid-April of 2023. 47 (43.93%) of respondents identified as African American and 54 (50.47%) as White. Familiarity with the concept of kidney transplantation and comfortability with kidney transplantation in relation to education level of survey respondents was found to be statistically significant with p-values of p=0.008 and p=0.02, respectively (with p-value of <0.05). Strictly within the White Race, statistical significance (write actual p-value) was found in comparing education level of respondents to familiarity with kidney transplantation, trust in the healthcare system to provide safe transplantation, likeliness to consider kidney donation, and comfortability with kidney transplantation.

Conclusions: Based on the analysis of the survey responses, we were able to determine the comfortability with kidney transplantation and familiarity with kidney transplantation have some relation to education level in kidney-disease patients located within Central Virginia. Based on such results, it is likely that organ donation apprehension continues to be rooted in culture. Future education initiatives should take these exhibited racial differences into account for success in striving for transplant equity.

PUB412

Identifying Barriers to Kidney Transplantation in a Veteran Population

Danish Waqar,[1,2] Kavitha Vellanki,[1,2] Manpreet Samra,[1,2] David J. Leehey.[1,2]
[1]Loyola University Medical Center, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL.

Background: Kidney transplantation is the treatment of choice for end-stage kidney disease patients and improves survival. The Edward Hines, Jr. VA Hospital recently became a regional referral center for kidney transplantation for Veteran patients. The kidney transplant referral process involves being timely seen by the pre-transplant evaluation team, completing all the necessary initial testing for transplant, and submitting a whole package through the transplant referral and cost evaluation/reimbursement (TRACER) process. Once TRACER is submitted, the transplant center has 5 days to review and accept or decline the evaluation. Not all patients get the workup completed or get evaluated for listing due to multiple factors. Our aim was to investigate the barriers to listing for kidney transplantation at our hospital.

Methods: We analyzed data from 45 patients from our hospital who were referred to the Hines VA transplant center from March 2019 through December 2022. All analyses were performed in R version 4.2.3, Foundation for Statistical Computing, Vienna, Austria. URL https://www.R-project.org/.

Results: Baseline characteristics of the patients are shown in the Table. The barriers identified are depicted in the Figure. Non-compliance of patients in completing the pre-transplant workup was the most frequent barrier, with other common barriers being delay in colonoscopy and presence of malignancy. A Kaplan-Meier estimate of median wait time from referral to evaluation revealed a marginal difference by age group, with longer wait times associated with increasing age.

Conclusions: There are multiple barriers to kidney transplant listing, with the most important being non-compliance of patients. This points toward improving patient education as a major focus to improving the pre-transplant evaluation process.

Funding: Private Foundation Support

PUB413

Providing Medication Education to Renal Transplant Recipients: Are We Getting It Right?

Sadia Jahan, Tiah Doody, Jasmine Goh, Hanh Tran. *Central and Northern Renal and Transplantation Service, Adelaide, SA, Australia.*

Background: Successful medication-taking behaviour by kidney transplant recipients is associated with long-term survival and is dependent on knowledge of medication regimens with medication counselling playing a major role in this. The optimal way of medication education delivery is not known, and our project is to evaluate current forms and to obtain feedback on alternative strategies. At our centre in Adelaide Australia, renal transplant recipients receive medication-related education from a clinical pharmacist in the post-transplantation phase in the form of verbal education and provision of a locally developed information booklet (seventeen A5 pages) and individualised medication list approximately 2-3 days post transplantation.

Methods: We utilised the validated Kidney Transplant Understanding Tool (K-TUT) to determine our patients' level of knowledge regarding their transplant medications. We also developed a patient survey assisting in classifying level of health literacy related to transplant medication knowledge.

Results: As part of feasibility, we present results from eight patients with 2/8 from Indigenous background and 2/8 patients' primary language being non-English. K-TUT scores were distributed between 41 and 66 (1 point for correct answer and 0 point for incorrect answer with total score of 69). In terms of the questions asked about preparedness for medicines post-transplant, direct quotes include "I was a bit nervous because I didn't realise there were so many tablets to start off with so that was a bit of a shock" and "No, I wasn't confident at first, I was a bit scared of how much tablet I had to take". One emerging theme is that the information booklet is not being read (7/8) with comments such as "I just didn't have time" and "I had so much going on". Another theme pertains to different delivery of education in the form of "mobile app would be good, (explaining) the tablets" and "A mobile app would probably be handy because the doctor and pharmacist can update it quickly".

Conclusions: Data from our patients have clear emerging themes, and it will be prudent to continue recruitment into the study, to clearly identify areas for improvement with knowledge about possible implementation of alternative education strategies.

PUB414

Bone Mineral Metabolism Alterations in Kidney Transplant Recipients in a Colombian Caribbean Fourth-Level Hospital

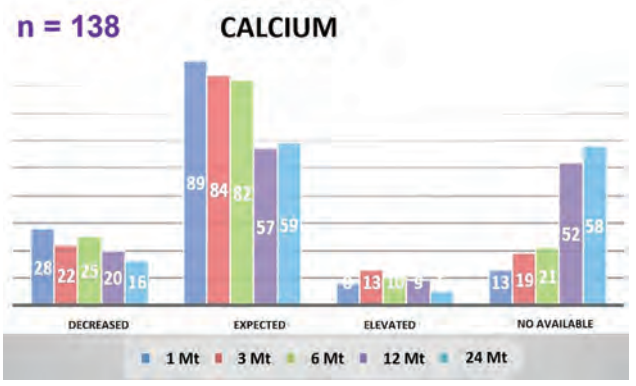
Karen G. Lasso,[1] Omar Cabarcas Barbosa,[1] William B. Riascos,[1] Alex Dominguez-Vargas,[2] Maria I. Pulgar,[3] Henry J. Gonzalez Torres,[1] Gustavo Aroca Martinez.[1] *[1]Universidad Simon Bolivar Facultad de Ciencias de la Salud, Barranquilla, Colombia; [2]Universidad del Norte Division Ciencias de la Salud, Barranquilla, Colombia; [3]Clinica de la Costa Ltda, Barranquilla, Colombia.*

Background: Bone mineral disorders are frequent in patients with chronic kidney disease (CKD). Renal transplantation inherits the morbid burden of the previous subject, increasing the risk of calcification disorders and cardiovascular disease. Surveillance should be strict in this population. The aim of this study is to describe the bone mineral metabolism alterations in renal transplant recipients in a fourth level hospital from the Colombian Caribbean.

Methods: A longitudinal study. Patients ≥18 years from the Local CKD Registry Cohort and functional renal allograft with at least 6 months of follow-up in the transplant program were enrolled. Clinical and laboratory variables from pathology follow-up examinations were retrospectively evaluated.

Results: A total of 138 patients, mostly men (59%), with a mean age of 43.7±12.3 years were included. A high prevalence of alterations in bone mineral metabolism was found: 78.36% at one-month post-transplant, 66.66% at 3 months, 69.56% at 6 months and 45.65% at 12 months. The most common alterations were: hyperparathyroidism (63%), hypocalcemia, hyperphosphatemia and hypovitaminosis D.

Conclusions: In this study, patients who underwent renal transplantation exhibited a significant prevalence of persistent hyperparathyroidism, irrespective of hypercalcemia. These findings highlight the critical need for diligent monitoring and effective management of bone mineral disorders in post-transplantation patients.



PUB415

Metabolic Profiles in Renal Transplantation: Assessing Hyperglycemia and Dyslipidemia Prevalence in Kidney Transplant Recipients from the Colombian Caribbean

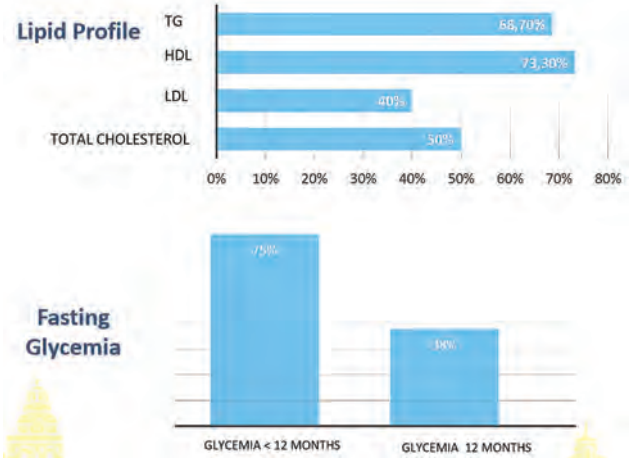
Karen G. Lasso,[1] William B. Riascos,[1] Omar Cabarcas Barbosa,[1] Alex Dominguez-Vargas,[2] Maria I. Pulgar,[3] Henry J. Gonzalez Torres,[1] Gustavo Aroca Martinez.[1] *[1]Universidad Simon Bolivar Facultad de Ciencias de la Salud, Barranquilla, Colombia; [2]Universidad del Norte Division Ciencias de la Salud, Barranquilla, Colombia; [3]Clinica de la Costa Ltda, Barranquilla, Colombia.*

Background: The renal transplant patient is at high risk of metabolic complications such as hyperglycemia, dyslipidemia, overweight, obesity and hyperuricemia. These conditions may affect the graft, cause early dysfunction and increase morbidity and mortality. The aim of this study was to determine the prevalence of metabolic disorders in renal transplant recipients in a fourth level hospital from the Colombian Caribbean.

Methods: This was a descriptive cross-sectional study that included patients aged 18 years and older from the Local CKD Registry Cohort with a functional renal allograft. Clinical and laboratory variables from pathology follow-up examinations were retrospectively evaluated.

Results: A total of 138 patients were included, mainly men (59%). The average age was 43.7±12.3 years. Mean paraclinical values were: glycemia 106.3±25.4 mg/dL, total cholesterol 206.5±37.6, LDL 117.9±62, HDL 37.1±8.2, VLDL55.6±26, and triglycerides 274.1±133 were recorded. Prevalence of altered lipid profile parameters and altered fasting glycemia were observed at different times during the period evaluated, including at 12 months post-transplantation.

Conclusions: In this study, the most common metabolic disorders in renal transplant recipients are hyperglycemia and dyslipidemia. Early detection and targeted interventions should focus on controlling hyperglycemia and dyslipidemia to mitigate the long-term consequences associated with these disorders in renal transplant recipients.



PUB416

De Novo Membranous Nephropathy and Humoral Rejection: A Different Presentation with a Shared Alloimmune Trigger

Ana C. Meira,[1] Geraldo S. Meira,[1] David C. Wanderley.[2] *[1]Hospital da Santa Casa de Montes Claros, Montes Claros, Brazil; [2]Instituto de Nefropatologia, Belo Horizonte, Brazil.*

Introduction: Membranous nephropathy (MN) is a glomerulopathy that can occur in a primary or secondary form. It is known that the primary form is related to the presence of autoantibodies against podocyte surface antigens, such as phospolipase A2 receptor (PLA2R) in up to 80% of cases. *De novo* MN has been described and related to humoral rejection, with the presence of circulating donor-specific antibodies (DSA) and biopsy findings of microvascular inflammation and C4d deposition in peritubular capillaries.

Case Description: A 26-year-old patient with CKD of unknown etiology underwent kidney transplantation from a deceased donor. The immunosuppression was tacrolimus and sodium mycophenolate. He had variable serum concentrations of tacrolimus despite maintenance of the dose, due to possible poor adherence. After 7 years of transplantation, he showed a significant increase in creatinine within a 3-month interval, as well as 24-hour proteinuria of 6 grams. He underwent a renal biopsy that demonstrated glomerular capillary loops with frequent spikes and holes, glomerulitis, 30-40% interstitial fibrosis and the presence of pericapillaritis. Immunofluorescence showed strong C4d deposition. Complementation of immunofluorescence with research for podocyte autoantibodies was requested, with positive research for IgG1, and negative for IgG4, PLA2R, THSD7A, NELL1, EXT1 and EXT2. DSA research showed the presence of antibody against HLA A1 (MFI: 13029). Intravenous immunoglobulin was administered, with partial improvement in creatinine. The patient evolved with graft loss 1 year after treatment.

Discussion: De novo membranous nephropathy after kidney transplantation may be associated with humoral rejection and be induced by alloimmune responses. The case above strengthens this hypothesis, as it fulfills the classic BANFF criteria for humoral rejection: presence of circulating DSA, glomerulitis and pericapillaritis on light microscopy and positive c4d on immunofluorescence. Furthermore, the search for the main autoantibodies involved in the pathogenesis of the primary nephropathy (IgG4, PLA2R, THSD7A, NELL1, EXT1 and EXT2) was negative, but positive for the IgG1 subclass that is related to de novo MN. The distinction between both is important for defining the treatment and prognosis.

PUB417

Zoom Before Clinic: How Telehealth Transforms Access for Kidney Transplantation Evaluation in the Post-COVID Era

Andrew J. Snyder,[1] Anna M. Morenz,[2] Jordan Nichols,[1] Omri Ganzarski,[1] Andre Dick,[3] James D. Perkins,[3] Nicole J. Kim,[2] Yue-Harn Ng.[2] *[1]University of Washington School of Medicine, Seattle, WA; [2]University of Washington Department of Medicine, Seattle, WA; [3]University of Washington Department of Surgery, Seattle, WA.*

Background: In 2020, In response to the SARS-CoV-2 pandemic, our center implemented a telehealth (TH) appointment option for kidney transplantation (KT) evaluation. TH has been shown to decrease travel time to clinic appointments and improve healthcare access for patients living in rural locations. It is unknown whether TH impacts KT patients' access to initial evaluation and waitlisting. We investigated the patient demographics of those who utilized TH for KT evaluation and the impact TH had on the early stages of KT evaluation.

Methods: We performed a retrospective cohort study of adults referred for KT evaluation from 01/31/2020 -12/31/2021. We compared baseline clinical and sociodemographic characteristics between patients who were 1) seen in person (IP) vs. seen via TH for their first KT clinic appointment and 2) whether TH impacted KT waitlisting.

Results: 620 patients were evaluated for KT during the study period, 343 (55.3%) attended their first appointment IP, 277 (44.7%) attended via TH. TH decreased the time from referral to evaluation by 22 days (117 vs 95; p<0.001). Patients who utilized TH lived further from the transplant center (34 vs 28 miles, p=0.01), were younger (55 vs 60 years; p=0.003), were more likely to be English speaking (93% vs 81%; p<0.001) and employed (37% vs 27%; p=0.009) and were less likely to be on dialysis (36% vs 52%; p<0.001). There was no significant difference in the rates of waitlisting between IP vs TH (31% vs 33%; p=0.3).

Conclusions: The use of TH services during early stages of the KT process decreases the time from referral to evaluation, but does not affect rates of waitlisting for KT. Inequities in TH use for KT evaluation are of concern meriting further attention to ensure equitable access.

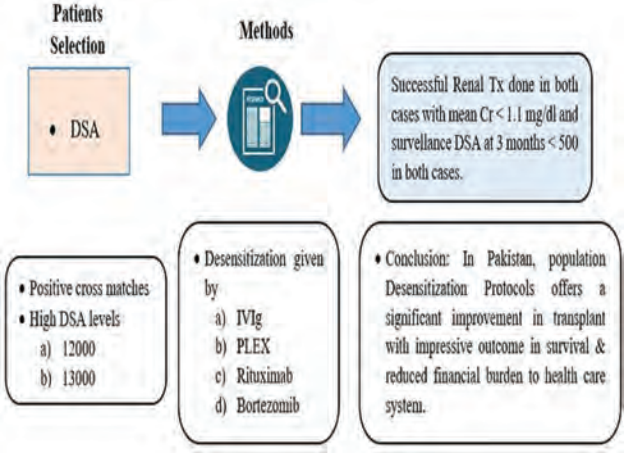
Desensitization Protocol in Pakistan: Is It Worth Doing? A Case Series

Nosheen Anjum, Zahid Nabi, Zahid ul Zahideen, Wasif Jamil. Transplant Team. *KRL Hospital, Islamabad, Pakistan.*

Introduction: Comparing with dialysis treatment for ESRD patients, renal transplant proffers significant survival and quality of life benefits. However, all-inclusive rates of transplantation still remain less for highly sensitized patients. For such cases, advanced approaches include (I) combinations of IVIg, rituximab, PE, bortezomib (II) pair donor exchange (PDE) (III) deceased donor allocation system (DDAS). At present, there are no guidelines for desensitization protocols and most of the published data is based upon * best practices * for desensitization that require individualization among patients. In countries like Pakistan with non-availability of PDE or DDAS, desensitization protocols should be utilized for highly sensitized patients.

Case Description: Methodology: We report two cases of highly sensitized live related renal transplant patients who underwent successful renal transplantation, after application of desensitization protocol using combination of IVIg, rituximab and PLEX in the first case and with addition of bortezomib to previously mentioned combination in second case. **Results:** Our first patient had positive DSA with MFI of 12000. After desensitization with combination of 2 Rituximab doses, 8 PLEX & IVIg, achieved MFI of 1700, and was therefore proceeded for renal transplant. In our second case, same protocol with addition of 3 doses of Bortezomib IV). DSA decreased significant to 2700 from 13000. Followup DSA at intervals of 1 and 3 months showed values in range of 400-600, Cr of 1.0 to 1.1mg/dl.

Discussion: Desensitization offers a significant improvement in renal transplant rates with impressive outcomes. In third world countries like Pakistan, where mostly adequate dialysis is not available and mortality rate is high, also overall financial burden is also a significant issue, performing renal transplant in highly sensitized population showed a preferable treatment option.



PUB419

Neurocognitive Concerns in Infants and Toddlers Awaiting a Kidney Transplant

Sarah J. Kizilbash, Finola E. Kane-Grade, Danielle Glad, Michael D. Evans, Lidan Gu. *University of Minnesota Twin Cities School of Medicine, Minneapolis, MN.*

Background: The KDIGO (Kidney Disease Improving Global Outcomes) guidelines suggest neurocognitive assessment in pediatric kidney transplant candidates with end-stage kidney disease (ESKD) before 5 years of age. However, there are limited data delineating the neuropsychological characteristics of infants and toddlers awaiting a kidney transplant.

Methods: Twenty-five infants and toddlers between ages 0 and 2 years completed the Bayley Scales of Infant and Toddler Development (3rd Edition and 4th Edition) at our center as part of their pre-transplant evaluations. Descriptive analyses were performed to summarize the distribution of characteristics within this population. We used one-sample t-tests to compare the standard scores of study participants with the population mean. Pearson correlations were used to examine the correlations between the Bayley scores and age at the evaluation as well as the dialysis duration.

Results: The mean age of this cohort was 1 year (SD 0.76). Within this cohort, 68% of patients were white, 72% were male, and 72% had congenital anomalies of the kidney and the urinary tract (CAKUT). Of all patients, 28% received no dialysis, while 44% received dialysis for more than 1 year. The mean dialysis duration was 432 days (SD 474 days). The mean scores of cognitive assessment (mean 86.7, SD 2.99), language assessment (mean 79.2, SD 2.81), and motor assessment (mean 78, SD 17.3) were significantly lower than the population means (t=-4.43, t=-7.40, t=-5.84, respectively, p<.001). We found a significantly positive correlation between age and motor scores (r=.45, p=0.04) and a significantly negative correlation between dialysis duration and Bayley subscales, including cognitive (r=-.50, p=0.02), language (r=-.62, p=.004), and motor scales (r=-.63, p=0.003).

Conclusions: We found a significant correlation between dialysis duration and cognitive, language, and motor scores on the Bayley Scales of Infant and Toddler Development among children awaiting a kidney transplant. Moreover, the cognitive, language, and motor scores of infants and children awaiting a kidney transplant are significantly lower than the population means. Infants and children in this group may benefit from early physical therapy, occupational therapy, and speech therapy.

Sex Differences in Non-Nephrologist Care Providers' Knowledge and Perceptions of Female Reproductive Health in CKD: A Survey Protocol

Tina Kim, Cameron Taheri, Sharanya Ramesh, Sofia B. Ahmed, Victoria J. Riehl-Tonn, Karen Fordham, Sandi M. Dumanski. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Chronic kidney disease (CKD) affects 12% of females globally and has important implications for reproductive health. Despite recommendations for multidisciplinary reproductive care, many females with CKD are managed independently by non-nephrologist care providers. This study aims to assess sex differences in non-nephrologist care providers' knowledge and perceptions of reproductive health in females with CKD.

Methods: A web-based survey will be developed following a literature review and consultations with experts in the field, as well as patient partners. Non-nephrologist care providers' knowledge and perceptions of reproductive health in females with CKD will be assessed, specifically as it relates to sexual health, menstruation, fertility, pregnancy, and menopause. Survey validity, clarity, and usability will be evaluated through pre-testing. The survey will be available in the world's 10 most commonly spoken languages. Snowball sampling will be employed via targeted emails to international and national reproductive healthcare provider organizations, as well as through social media platforms.

Results: Numeric and Likert-scale survey responses will be descriptively analyzed and free-text survey responses will undergo conventional content analysis. All results will be stratified by sex.

Conclusions: An improved understanding of sex differences in non-nephrologist care providers' knowledge and perceptions of female reproductive health in CKD can help identify gaps in care delivery and optimize reproductive health for this underserved population.

PUB421

Clinicopathological Study of Nine Cases of Proteinuria in Pregnancy, Including Hypertensive Disorders of Pregnancy

Rei Nakazato,[1] Akiko Mii,[1] Akira Shimizu,[2] Yukinao Sakai.[1] [1]*Nihon Ika Daigaku Fuzoku Byoin, Bunkyo-ku, Japan;* [2]*Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Introduction: Advanced maternal age is a risk factor for prenatal complications including hypertensive disorder of pregnancy (HDP). Furthermore, severe proteinuria during pregnancy suggests the possibility of HDP and/or pregnancy-related renal complications, increasing the risk of worsening maternal renal prognosis.

Case Description: Over the past seven years, we experienced nine pregnant cases with severe proteinuria that required intervention from the internal medicine department. The average maternal age of all cases was 37.6 years old, and seven of the patients were advanced age pregnancy (>35 years old). Among the cases, seven presented nephrotic

syndrome (NS) and eight patients underwent renal biopsy, revealing in IgA nephropathy (n=1), minor change NS (MCNS) (n=2), focal segmental glomerulosclerosis (FSGS) (n=3), and thrombotic microangiopathy (n=2). Five patients were diagnosed with HDP and their mean gestational age at diagnosis was 36 weeks, with blood pressure (BP) of 155/86 mmHg, and urinary protein (U-P) level of 9.5 g/g Cr at any time. All HDP cases received antihypertensive therapy. Three of them improved proteinuria through medication alone, one required continuous hemodiafiltration for pulmonary edema after birth, and another case received plasmapheresis for obstetrical DIC and acute kidney injury. The four non-HDP patients were diagnosed at a mean gestational age of 27 weeks, with a BP of 122/74 mmHg, and U-P level of 7.34 g/g Cr at any time. These cases included IgA nephropathy, FSGS (cellular variant and tip variant), and MCNS, respectively, and underwent steroid therapy resulting in remission.

Discussion: We encountered nine cases of proteinuria in pregnancy, including HDP cases. A majority of the patients were of advanced maternal age, which is considered a risk factor for HDP. Our findings suggest that antihypertensive therapy can be expected to improve severe urinary protein levels in HDP cases although their histopathological findings were varied. On the other hand, it was crucial to identify the cause of proteinuria and to treat the underlying disease appropriately. Therefore, it is also important to perform renal biopsies whenever possible.

Perceptions of Gynecologic Health and Health Care in Females Living with CKD: A Survey Protocol

Tessa A. Woodside,[1] Victoria J. Riehl-Tonn,[1] Sofia B. Ahmed,[1] Erin A. Brennand,[1] Meghan J. Elliott,[1] Danica H. Chang,[2] Karen Fordham,[1] Sandi M. Dumanski.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Chronic kidney disease (CKD) affects more than 12% of females globally and its prevalence is increasing rapidly. CKD is often accompanied by gynecological health complications, with implications for menstruation, menopause, sexual health, fertility, and pregnancy. However, patient perceptions of gynecologic health and healthcare in females living with CKD are poorly understood. This study aims to assess the perceptions of gynecologic health and healthcare of females living with CKD.

Methods: An exploratory web-based survey will be developed following a thorough literature review and after consulting with experts in the fields of nephrology and gynecology, and with the engagement of patient partners. The questions will address patient perceptions of gynecologic health and healthcare-related to menstruation, menopause, sexual health, fertility, pregnancy, and urinary incontinence. Survey pre-testing with patient partners will assess face validity, clarity, length, usability, and technical functionality. The web-based survey will utilize adaptive questioning to help reduce survey complexity. Self-identified adult females with CKD will be invited to participate through national and international CKD patient organizations, as well as through social media platforms.

Results: Numeric responses will be analyzed using descriptive statistics and open-ended responses will be analyzed using conventional content analysis.

Conclusions: This study will be the first to our knowledge to assess comprehensive gynecologic health and healthcare-related perceptions of females living with CKD, and will aid in the integration of patient perspectives into future research and clinical initiatives.

Biomarker Associations with Kidney Failure and Death

Oskar Ålund,[1] Robert J. Unwin,[2] Philip A. Kalra,[4,3] Maarten W. Taal,[5] Magnus Soderberg.[1] On Behalf of the NURTuRE Investigators. *[1]AstraZeneca PLC, Gothenburg, Sweden; [2]AstraZeneca PLC, Cambridge, United Kingdom; [3]The University of Manchester, Manchester, United Kingdom; [4]Salford Royal Hospital, Salford, United Kingdom; [5]University of Nottingham, Nottingham, United Kingdom.*

Background: The NURTuRE CKD cohort comprises a wide range of biomarker measurements and outcome data for 2996 CKD patients based in the UK. A comparative study that outlines the relative importance of various biomarkers with respect to predicting mortality and kidney failure (KF) is of interest in biomarker selection for future studies.

Methods: Using biomarker data from the NURTuRE CKD cohort, we compared the means of patients who suffered KF (defined as dialysis start or transplant) or death within 2 years versus those who did not. A log-transform was applied to biomarkers with skew > 4, and a square root transform to biomarkers with skew between 1 and 4. After these transformations, all skews were within -1 and 1. Mean biomarker differences in the positive and negative groups were then assessed by computing deviations from the negative group means, scaled by the standard deviations of the negative group.

Results: Figure 1 shows mean biomarker differences scaled by standard deviation. For example, the first blue bar indicates that eGFR (after normalization) was about 1.25 standard deviations lower on average in patients who suffered kidney failure within 2 years compared with those who did not. Similarly, the first orange bar indicates 0.5 standard deviations lower eGFR in patients who died within 2 years compared with those who did not. The markers associated with the 4 largest differences for kidney failure were eGFR, serum-Creatinine, serum-Cystatin C, and Urine-ACR. The markers associated with the 4 largest differences for death were serum-Troponin, Age, serum-brain natriuretic peptide (BNP), and serum-growth differentiation factor-15 (GDF15).

Conclusions: The top four biomarkers associated with mortality (Troponin, Age, BNP, GDF15) are distinct from the top four biomarkers of kidney failure (eGFR, Creatinine, Cystatin-C, ACR). Perhaps unsurprisingly, the kidney failure markers are all related to kidney function, whereas the mortality markers are related to cardiac disease.

PUB424

The Variation of Estimated Glomerular Filtration Rate (eGFR) with Changes of Body Weight and Body Composition in a Health Check-Up Cohort Without CKD

Soomin Kim,[1] So Young Jang,[1] Ho Jun Chin.[2,1] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Obesity is well known risk factor to chronic kidney disease, cardiovascular disease, and mortality. However, the effect of weight change within normal weight range on renal function has not been studied, well.

Methods: We enrolled non-CKD participants who had repeated routine health check-up at baseline, one-year, and three-year follow-up period. We measured fat-free weight (FFW) and fat-free percent (FFP) in body weight by InBody test. We analyzed the relationship between changes of body weight, BMI, FFW, and FFP during one-year follow-up period and variation of eGFR during three-year follow-up period. We define rapid decline of renal function as a decrease in eGFR ≥ 5 ml/min/1.73 m^2/year.

Results: Enrolled 1837 participants had eGFR of 101.1 (60.2~187.5) ml/min/1.73 m^2 and urine proteinuria by dipstick test less than one positive. Indicators of body composition were body weight of 66.8 (39.5~117.4) kg, BMI of 23.7 (15.2~36.2) kg/m2, FFW of 53.1 (30.9~78.1) kg, and FFP 78.4 (59.4-95.5) % at baseline examination. During one year period, the change of eGFR was related to percent change of FFP (factor B=0.197, p=0.012) and FFW (factor B=0.347, p<0.001), positively. There were 366 (19.9 %) participants with rapid decline of eGFR during 3 years. With multiple logistic regression analysis, the factors related to rapid decline of eGFR during 3 years were the percent change of FFW [RR 1.054 (95% CI: 1.011-1.099), p=0.013, Table]. With the quintile group of percent change of FFW, multiple logistic regression to estimate rapid decline of eGFR showed increased relative risk to 1.400 (95% CI: 1.009-1.943, p=0.008) in highest quintile group compared to third and fourth quintile group.

Conclusions: During short-term period, the change of fat-free weight was related to increase of eGFR, however, it was related to decline of renal function in long-term period. That suggested initial glomerular hyperfiltration by increase of fat-free weight would have resulted in decline of eGFR in the end.

Table. Multivariate logistic regression to detect risk factors for rapid decrease in renal function during 3 years

	Factor B	Wald	RR	95% CI of RR		p-value

Prevalence of Asymptomatic Urinary Leptospira Carriage Among Young Adults at Risk of Mesoamerican Nephropathy

Ali M. Al-Rashed,[1] Marvin A. Gonzalez,[1,3] Amin Oomatia,[1] Dorothea Nitsch,[2] Neil Pearce,[2] Cordelia Coltart,[1] Ben Caplin.[1] The Colt/UK MRC CKDu Study Group. *[1]University College London, London, United Kingdom; [2]London School of Hygiene & Tropical Medicine, London, United Kingdom; [3]Universidad Nacional Autonoma de Nicaragua, León, Nicaragua.*

Background: Leptospirosis is a bacterial zoonosis with a range of clinical manifestations including acute kidney injury. Chronic carriage of leptospira is well-described in several species, but it remains unclear whether this occurs in humans. Furthermore, chronic experimental infection with leptospira is associated with progressive

kidney injury in small animal models and asymptomatic carriage of leptospira has been proposed as a cause of CKD of unknown aetiology, one form of which is Mesoamerican Nephropathy (MeN). Determining the burden of asymptomatic leptospiral infection is challenging as serological assays may not be sensitive to antibodies against all serovars and immunity may wane over time. We therefore explored the evidence for asymptomatic carriage of urinary leptospira in a young adult population at risk of MeN.

Methods: Samples were analysed at multiple timepoints per individual from a community-based, longitudinal study of apparently healthy young adults (mean age = 24.2, mean baseline eGFR = 110.5 ml/min/1.73m^2, % male = 83.2) from rural north-west Nicaragua followed-up annually for 7 years. Serum anti-leptospira IgG antibodies were measured in 346 participants using a commercial ELISA kit and an established nested 16S PCR method was used to screen for leptospiral DNA in urine in 94 participants. Sanger sequencing was used to confirm leptospiral species in a subset of 16S PCR positive samples.

Results: None of the participants had recent symptoms of acute leptospiral illness. 55 (59%) participants were 16S PCR positive at ≥1 timepoint and 18% were positive at 2 timepoints. Sequencing of a subset demonstrated 29% of 16S PCR positive samples were consistent with leptospiral DNA, suggesting an overall prevalence of asymptomatic carriage of 17%. Overall, 8.7% (30/346) of participants tested IgG positive for leptospira in at least one timepoint of whom 12 seroreverted at follow-up testing. Rates of seropositivity were similar between 16S PCR positive and negative groups.

Conclusions: Asymptomatic urinary shedding of leptospires is common in a young population at risk of MeN which appears to be persistent or recurrent in some cases. Serological assays do not reliably identify individuals shedding urinary leptospiral DNA.

PUB426

Albuminuria and Incident Atrial Fibrillation in Community-Dwelling Adults: The REGARDS Study

Joseph J. Crivelli,[1] Ashutosh Tamhane,[1] Rajat Deo,[2] Elsayed Z. Soliman,[3] Gabriela R. Oates,[1] Virginia J. Howard,[4] Michael Shlipak,[5] Suzanne E. Judd,[4] Mary Cushman,[6] Orlando M. Gutierrez.[1] *[1]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]The University of Alabama at Birmingham School of Public Health, Birmingham, AL; [5]University of California San Francisco, San Francisco, CA; [6]University of Vermont Larner College of Medicine, Burlington, VT.*

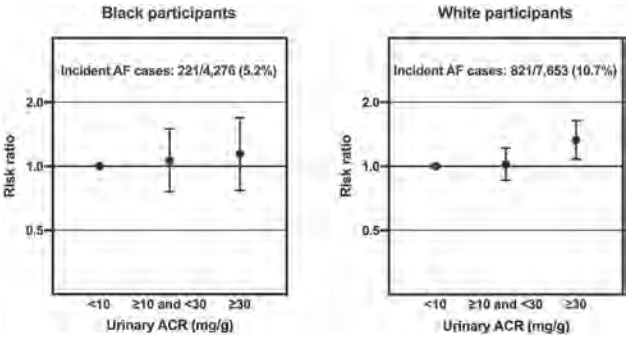
Background: Higher urinary albumin-to-creatinine ratio (ACR) is associated with increased risk of atrial fibrillation (AF). ACR is more strongly associated with incident stroke and coronary heart disease in Black compared to White adults. We aimed to determine whether similar racial differences exist for AF.

Methods: Prospective cohort study of community-dwelling adults ≥45 years old enrolled in the Reasons for Geographic and Racial Differences in Stroke (REGARDS) study. Modified Poisson regression with robust variance estimates was used to examine the association of ACR measured at the baseline visit with the validated outcome of incident AF based on electrocardiogram or self-report of physician-diagnosis at the second in-home visit approximately 10 years later. Models were adjusted for demographic variables and AF risk factors including eGFR.

Results: Among 11,929 participants (mean age 63 years, 45% male, 36% Black), there were 1,042 (8.7%) with incident AF. In the fully adjusted model (see Figure), compared to ACR <10 mg/g, the association between ACR and incident AF did not differ between Black (RR_{adj}=1.06; 95% CI: 0.76-1.47) and White (RR_{adj}=1.06; 95% CI: 0.89-1.25) participants in the ACR ≥10 and <30 mg/g category. In contrast, compared to ACR <10 mg/g, ACR ≥30 mg/g was associated with greater risk of incident AF in White (RR_{adj}=1.33; 95% CI: 1.08-1.64) but not in Black (RR_{adj}=1.14; 95% CI: 0.77-1.69) participants, although the multiplicative interaction term was not significant (p=0.84).

Conclusions: The association between urinary ACR and incident AF did not appreciably differ by race.

Funding: Other NIH Support - This research project is supported by cooperative agreement U01 NS041588 co-funded by the National Institute of Neurological Disorders and Stroke (NINDS) and the National Institute on Aging (NIA), National Institutes of Health, Department of Health and Human Service.



RRs and 95% CIs for incident AF among Black and White participants by ACR categories. The model was adjusted for age, sex, and geographic region of residence, education, income, smoking, alcohol consumption, waist circumference, exercise, systolic blood pressure, cholesterol, coronary heart disease, stroke, diabetes, statins, antihypertensives, RAAS inhibitors, and eGFR.

Associations of Causes of CKD with Disease Progression and Mortality: Insights from the Fukuoka Kidney disease Registry (FKR) Study

Hiromasa Kitamura,[1,2] Shigeru Tanaka,[2] Hiroto Hiyamuta,[4] Kazuhiko Tsuruya,[3] Takanari Kitazono,[2] Toshiaki Nakano.[2] *[1]Fukuoka Shika Daigaku, Fukuoka, Japan; [2]Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan; [3]Nara Kenritsu Ika Daigaku, Kashihara, Japan; [4]Fukuoka Daigaku, Fukuoka, Japan.*

Background: The Kidney Disease: Improving Global Outcomes guidelines recognize the significance of causes of chronic kidney disease (CKD), glomerular filtration rate, and albuminuria as predictors of kidney outcome and prognosis. However, limited research has explored the relationship between clinically-diagnosed causes of CKD and prognosis, in comparison to biopsy-proven causes.

Methods: We examined 3,119 patients with non-dialysis-dependent CKD who participated in the Fukuoka Kidney disease Registry Study, a multicenter prospective cohort study. Patients were divided into six groups: IgA nephropathy, chronic glomerulonephritis (non-biopsy-proven), diabetic nephropathy, hypertensive nephrosclerosis, chronic interstitial nephritis, and polycystic kidney disease. The primary outcomes included a composite kidney outcome, defined by a 1.5-fold increase in serum creatinine and/or development of end-stage kidney disease, and all-cause mortality. The risks for these outcomes were estimated using a Fine–Gray proportional subdistribution hazards model. IgA nephropathy, the most prevalent primary glomerulonephritis, served as the reference group.

Results: During the median follow-up period of five years, 1,221 patients developed the composite kidney outcome, and 346 patients died. Compared to IgA nephropathy, the multivariable-adjusted subdistribution hazard ratios (sHRs) for the composite kidney outcome were significantly higher in diabetic nephropathy (sHR 1.45) and polycystic kidney disease (sHR 2.07), while chronic interstitial nephritis showed a significantly lower risk (sHR 0.71). The risk of all-cause mortality was significantly higher in hypertensive nephrosclerosis (sHR 1.90).

Conclusions: The causes of CKD were associated with the risks of the composite kidney outcome and all-cause mortality, underscoring their clinical relevance in predicting prognosis. These findings suggest that different causes of CKD have distinct impacts on patient outcomes, emphasizing the importance of tailored management strategies based on the underlying causes.

PUB428

Influence of Consecutive AKI Episodes on CKD Progression

Isabel Acosta-Ochoa, Armando Coca, Paula Ardura, Carlos L. Merizalde Moscoso, Sandra Sanz, Maria Martinez, Kenia P. Cobo Campuzano, Alicia Mendiluce. *Hospital Clinico Universitario de Valladolid, Valladolid, Spain.*

Background: Is a well-known fact that AKI leads to progression of preexisting CKD. Despite this evidence, we find that some patients after successive AKI episodes progress and some that do not. We aimed to study potential risk factors for worsening CKD stage when suffering from AKI on CKD (AoCKD) besides AKI severity.

Methods: Retrospective, study of hospitalized patients that suffered at least 3 AoCKD episodes during a 4-y period. We defined progression as the change to a higher CKD stage compared to the stage of the first AoCKD event, or HD dependence at discharge. In-hospital mortality was not considered an indicator of progression. We defined high Charlson's (ChI) as Score ≥3, classified AKI with the KDIGO-2012 criteria, compared clinical variables and searched for risk factors for progression.

Results: We included 458 AoCKD episodes of 129 individuals. 58 (45%) progressed, 13 were HD dependent at discharge (22% of progressors); they had a higher ChI, were classified in KDIGO-AKI stage 3 and needed acute HD more frequently. We found no statistically significant differences in age, admission in ICU, time to nephrology consultation, KDIGO-AKI stage 2, and in-hospital mortality (Table 1A-B). When analyzing variables, we found risk factors for progression OR: Need for

HD 2.98 (1.22–7.27), KDIGO-3 stage 3.00 (1.46–6.16), High ChI 8.6 (1.10–69.70), and being hospitalized in a Medical Ward 2.22 (1.22–4.10) (Table 2).

Conclusions: We found that relatively less patients are progressors, could this finding be explained because CKD confers a physiological adaptation to AKI? We observed that factors that promoted CKD progression were: AKI severity in a dose dependent manner; High ChI ≥3, need for HD and being hospitalized in medical ward, due to a skew of no-progressors being hospitalized in surgical wards? All these factors are not modifiable, so we should be more creative and search for non-traditional factors to try to find modifiable ones, to tackle CKD progression due to AoCKD.

Nonalcoholic Fatty Liver Disease (NAFLD) and Sarcopenia in CKD Stages 1-5 Non-Dialysis Patients

Secundino Cigarran,[1] Juan Carlos Primo,[2] Lucía Grela,[1] Ana Maria Sanjurjo Amado,[3] Maria Jesus Corton Cabo,[3] Jesus Calvino Varela.[4] *[1]Nephrology, Hospital Ribera Polusa, Lugo, Spain; [2]Nephrology Research Unit, Hospital Publico da Mariña, Burela, Spain; [3]Nephrology, Hospital Publico da Mariña, Burela, Spain; [4]Nephrology, Hospital Lucus Augusti, Lugo, Spain.*

Background: NAFLD is a chronic liver disease characterized by excess fat accumulation in the liver. It is associated with metabolic syndrome and often has comorbidities such as obesity, diabetes, and dyslipidemia. NAFLD has been associated with various non-liver comorbidities, including cardiovascular disease, CKD, and sleep apnea, closely related to Sarcopenia. Sarcopenia, defined as low muscle mass and impaired muscle function, is associated with NAFLD and worse outcomes. This crossover study aims to assess the prevalence of Sarcopenia in CKD patients with NAFLD evaluated by bioelectrical impedance (BIA).

Methods: 854 CKD pts, age 72,02(14,07),40.2% female, 41.2%, DM2, 48.4% obese men (%fat mass>25%) and 29% obese female (% fat mass >35%), GFR-EPI 51.6 (26.8) ml/min/1.73m2, UACR 258.36 (630), were enrolled. NAFLD was evaluated by BIA (Bioscan I8, Maltron, London) using the manufacturer software based on the fat/muscle ratio, staging NAFLD in 5 stages (0-4). Sarcopenia defined as EWGSOP2 (2018); cut-off points for dynapenia <27kg for men and <16kg for women of dominant arm muscle strength and muscle mass <20kg male and <15kg female. AGEs by autofluorescence were read by (DiagnOtics, Groningen, Netherlands)), and vascular Age was obtained from the Koetsier equation(AGEs0.83)/0.24. Data were processed with SPSS 27. A p-value <0.05 was considered statistically significant.

Results: NAFLD incidence was 89.8%. 36.9% female and 63.1% men. Obese 86.4% and Diabetic 94%. Sarcopenia was identified in 6 men (1.23%) and 12 women (4.24%) p<0.001. Comparing NAFLD all stages vs Non-NAFLD: %Fat mass 35 (8.39) vs 27,58 (8.03)% (p<0.001); GFR-EPI 50.09(25.5) vs 66.14(32.09) (p<0.001). Vascular age-age : 16.7(25) vs 14.74(p<0.001). Stages incidence: Healthy 10.2%; Stage1 10.7%; Stage2 15.1%, Stage3 17.4% Stage 4(severe)46.6%. UACR 257.6 (629) vs 265 (638) (NS).

Conclusions: NAFLD is highly frequent in CKD patients-associated obesity, DM2 and lower GFREPI. Unexpectedly, according to EWGSOP2 (2018) criteria, Sarcopenia is scant, more frequent in women. NAFLD related parameters were %fat Mass, DM2, obesity, GFR-EPI and average of vascular age, showing an inflammatory and premature aging status. BIA is a valuable tool, non observer dependent, non-invasive and easy to use.

Results from a Chinese Multispecialty Delphi Consensus to Optimize Renin-Angiotensin-Aldosterone System Inhibitor (RAASi) Usage and Hyperkalaemia (HK) Management in Patients with CKD and Heart Failure (HF)

Ming-Hui Zhao,[1] Wei Chen,[2] Hong Cheng,[3] Bi-Cheng Liu,[4] Zhiguo Mao,[5] Zhuang Tian,[6] Gang Xu,[7] Jingmin Zhou.[8] *[1]Peking University First Hospital Department of Nephrology Renal Division, Beijing, China; [2]Sun Yat-sen University First Affiliated Hospital, Guangzhou, China; [3]Capital Medical University, Beijing, China; [4]Southeast University Zhongda Hospital, Nanjing, China; [5]Shanghai Changzheng Hospital, Shanghai, China; [6]Peking Union Medical College Hospital, Dongcheng-qu, China; [7]Huazhong University of Science and Technology Tongji Medical College, Wuhan, China; [8]Zhongshan Hospital Fudan University, Shanghai, China.*

Background: This consensus aims to establish a multi-speciality approach to the optimal use of RAASi and management of hyperkalemia (HK) in patients with CKD and HF.

Methods: A steering group of cardiology and nephrology experts from across China convened to discuss challenges to HK management and the optimal use of RAASi. 41 statements for a consensus questionnaire were created and distributed further among cardiologists and nephrologists across 21 provinces in China. Consensus was assessed using a modified Delphi technique, with agreement defined as 'strong' (≥75% and <90%) and 'very strong' (≥90%). The result was also compared with those from a similar consensus in Europe and North America (E&NA).

Results: A total of 150 responses from China were received evenly distributed between cardiologists and nephrologists. All statements achieved the 75% consensus agreement threshold, which includes identification of risk factors for HK in cardiorenal patients, preventive measurements and correction of hyperkalaemia for patients at risk of HK, cross-specialty alignment between Cardiology and Nephrology, and education of clinicians and patients. Some variation was identified between E&NA and China responses regarding to the maintenance of RAASi therapy at a maximal dose in the face of HK, but generally there was broad agreement across common statements.

Conclusions: Based on the agreement levels from respondents, the steering group were able to create a compelling set of recommendations to improve patient outcomes with RAASi therapy and HK management in China.

PUB431

Can Serum Sodium Minus Chloride Level at the Initiation of Angiotensin-Converting Enzyme Inhibitors or Angiotensin Receptor Blockers in CKD Patients Predict New Onset of Hyperkalemia?

Haruki Mae, Takuya Fujimaru, Kotaro Shimoyama, Nozomi Kadota, Kasumi Konishi, Yugo Ito, Masahiko Nagahama, Fumika Taki, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

Background: ACE inhibitor (ACE-I) and angiotensin receptor blocker (ARB) have renoprotective effect on chronic kidney disease (CKD) patients. However, one of their side effects is hyperkalemia, and it is associated with poor prognosis in CKD patients. Although hyperchloremic acidosis is known as a risk factor for hyperkalemia in CKD patients, it is unclear whether hyperchloremic acidosis at the initiation of ACE-I or ARB is a risk factor for hyperkalemia after initiation of these drugs.

Methods: We conducted a retrospective observational study in a single hospital. Non-dialysis CKD patients who were initiated on ACE-I or ARB between January 2011 and December 2021 were enrolled. Because serum bicarbonate level is not routinely measured, we defined hyperchloremic acidosis as serum sodium minus chloride level ([Na] - [Cl]) < 36 mEq/L from the physiological approach. The eligible patients were divided into groups with and without hyperchloremic acidosis at the initiation of ACE-I or ARB. The primary outcome was hyperkalemia, defined as serum potassium level ([K]) > 5.0 mEq/L at the first blood test after the initiation. Multivariate logistic regression analysis was performed adjusted by baseline data; age, sex, diabetes, eGFR, [K], hypoalbuminemia, and use of drugs that influence [K].

Results: In this study, 1143 patients were enrolled, and 766 patients (67%) had [Na] - [Cl] < 36 mEq/L at baseline. In multivariate analysis, only eGFR and [K] at initiation were significantly associated with hyperkalemia (odds ratio (OR);95% confidence interval (CI) were 0.96;0.93–0.98 and 5.99; 2.50–15.6, respectively). From the subgroup analysis which included the patients who were measured [Na] - [Cl] after the initiation as well, of the 353 patients with [Na] - [Cl] ≥ 36 mEq/L at baseline, 150 patients (42.4%) developed hyperchloremic acidosis after the initiation. Additionally, [Na] - [Cl] < 36 mEq/L after the initiation was significantly associated with hyperkalemia in multivariate analysis (OR 2.45; 95% CI 1.15–6.06).

Conclusions: ACE-I or ARB may affect the acid-base status of CKD patients. Therefore, [Na] - [Cl] < 36 mEq/L at the initiation of these drugs could not predict newly onset hyperkalemia.

PUB432

Clinical Characteristics, Treatment Patterns, and Renal-Related Events in Patients with Diagnosed CKD: Results from Regional Health Information System in China

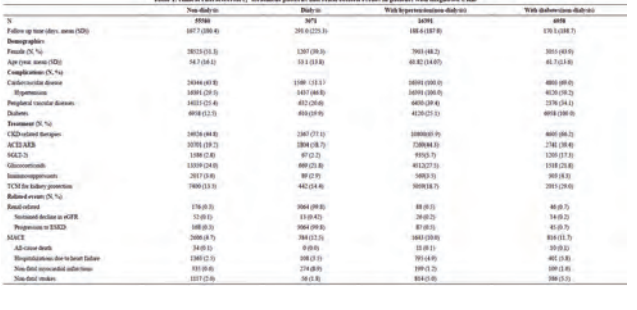
Buyun Wu, Kang Liu, Huijuan Mao. *Department of Nephrology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The clinical characteristics, treatment patterns and renal-related events of diagnosed chronic kidney disease (CKD) provide evidence that can improve CKD management. However, the situation in China remains under-investigated.

Methods: We included adults with electronic health records (2020.01-2021.12) in Xuzhou, China. Clinical diagnosis of CKD was defined as having diagnostic keywords and International Classification of Disease (ICD)-10 codes related to primary cause or stages of CKD. All patients with diagnosed CKD were required to have at least one follow up visit after being enrolled, and were further categorized into dialysis and non-dialysis groups. Among the non-dialysis, individuals diagnosed with hypertension and diabetes were categorized as two independent subgroups.

Results: A total of 58,651 patients with diagnosed CKD were identified, including 55580 non-dialysis and 3071 dialysis individuals. Cardiovascular diseases accounts for 43.8% of all non-dialysis individuals, followed by peripheral vascular disease (25.4%) and diabetes (12.5%). 44.8% of all non-dialysis patients had received CKD-related therapies, including ACEI/ARB (19.2%), SGLT-2i (2.8%), glucocorticoids (24.0%), immunosuppressants (3.6%), traditional Chinese medicine for kidney protection (13.3%), et al. A total of 176 renal-related events (0.3%) occurred during follow-up period, including 52 cases of sustained decline in eGFR and 168 cases of progression to ESKD. Besides, 2606 individuals experienced MACE events (4.7%). Compared to the general population of non-dialysis patients, individuals with hypertension or diabetes had higher incidence of renal related events (hypertension:0.5%, diabetes:0.7%) and MACE events (hypertension:10.0%, diabetes:11.7%).

Conclusions: Patients with diagnosed CKD in this cohort frequently complicate cardiovascular diseases. Despite being diagnosed with kidney disease, the proportion of individuals receiving CKD-related therapies remains low, and the incidence of renal-related and MACE events should be noticed.



PUB433

Hospitalizations Among Adults with CKD: Results from KNOW-CKD Study

Yeongwon Park, Minsang Kim, Eunjeong Kang, Hyunjin Ryu, Kook-Hwan Oh. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) patients are hospitalized for various causes. Hospitalization increases the readmission rate and mortality rate, seriously deteriorating patients' quality of life. For this reason, it is crucial to analyze the causes of hospitalization in CKD patients in a broader perspectives according to CKD grades.

Methods: This study was conducted as a prospective cohort of CKD patients, entitled KoreaN Cohort Study for Outcomes in Patients With Chronic Kidney Disease (KNOW-CKD). A total of 2,238 patients were examined in this study, and the causes of hospitalization were classified into 16 disease categories. The incidence rate ratio (IRR) according to CKD grade was compared using Poisson regression analysis. Hospitalization ratio of KNOW-CKD patients was also compared with hospitalization data of general population procured from Korea National Sample Cohort Database.

Results: The all-cause hospitalization incidence was 184.96 per 1000 person-years. The most common cause of hospitalization was circulatory system disease, followed by infection and digestive system disease. When analyzing the incidence rate of all-cause hospitalization according to the CKD grades, patients had an incidence of 101.99, 143.68, 193.86, and 310.11 per 1000 person-years. In the hospitalizations for acute kidney injury, endocrine, nutrition, metabolic related cause, nervous system disease, and genitourinary system, the IRR increased as the grade advanced. IRR of KNOW-CKD patients was 5.92(95% CI; 5.66-6.19; P-value<0.001) compared to general population.

Conclusions: CKD patients were hospitalized for various causes, with incidence increased by grades. Thus, early detection and intervention is tremendously important to reduce hospitalization burden and improve patients' quality of life.

Results from a Cross-Specialty Consensus on Optimal Management of the CKD Patient: From Screening to Complications

Mustafa Arici,[1] Samir H. Assaad-Khalil,[2] Marcello Bertoluci,[3] Jason Choo Chon Jun,[4] Yau-Jiunn Lee,[5] Magdalena Madero,[6] Guillermo J. Rosa Diez,[7] Vicente Sanchez Polo,[8] Sungjin Chung,[9,10] Teerawat Thanachayanont Thanachayanont,[11] Carol A. Pollock.[12] *[1]Hacettepe Universitesi, Ankara, Turkey; [2]Alexandria University Faculty of Medicine, Alexandria, Egypt; [3]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [4]Singapore General Hospital, Singapore, Singapore; [5]Lee's Endocrinology Clinic, Pingtung, Taiwan; [6]Department of Medicine, National Heart Institute, Mexico City, Mexico; [7]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [8]Instituto Guatemalteco de Seguridad Social, Guatemala, Guatemala; [9]The Catholic University of Korea School of Medicine, Seoul, Republic of Korea; [10]Korean Society of Nephrology, Seocho-gu, Seoul, Republic of Korea; [11]Bhumirajanagarindra Kidney Institute, Bangkok, Thailand; [12]Kolling Institute of Medical Research, St Leonards, NSW, Australia.*

Background: Chronic kidney disease (CKD) affects around 10% of the global population and has been estimated to affect around 50% of individuals with type 2 diabetes and 50% of those with heart failure. The guideline recommended approach is to manage with disease-modifying therapies, but real-world data suggests that prescribing rates do not reflect this in practice. We wished to establish consensus on optimal management of the CKD patient.

Methods: An international steering group of experts specialising in internal medicine, endocrinology/diabetology, nephrology and primary care medicine developed 42 statements on aspects of CKD management including identification and screening, risk factors, holistic management approach, guidelines, cross-specialty alignment, and education. Consensus was determined using an online survey. The survey was distributed to cardiologists, nephrologists, endocrinologists, and primary care physicians across 11 countries. The threshold for consensus agreement was established *a priori* by the steering group at 75%.

Results: 274 responses were received, 25 responses from Argentina, Australia, Brazil, Guatemala, Mexico, Singapore, South Korea, Taiwan, Thailand, Turkey, and 24 responses from Egypt: 53 responses from cardiologists, 52 from nephrologists, 55 from endocrinologists, and 114 from primary care physicians. 37 statements attained very high agreement (≥90%) and 5 attained high agreement (≥75% and <90%). Strong alignment between roles was seen across the statements, and across different levels of experience (2-5 years or 5+ years), some variation was observed between countries.

Conclusions: There is a high degree of consensus regarding aspects of CKD management among healthcare professionals. Based on these strong levels of agreement, the steering group derived twelve key recommendations focused on diagnosis and management of CKD. Two key recommendations are provided below: - Early screening for CKD in high-risk groups using eGFR and uACR as the screening method of choice is cost-effective for the health system - Intervene early in CKD patients with proven therapies (i.e., SGLT2i, RAASi, DMTs) to delay/prevent progression to kidney failure

Predictors of Disease Progression in Patients with CKD: Results from a Real-World Study

James Jackson, Dean A. Taylor, Muhammad Jamee, Sophie Barlow, Mollie Lowe. *Adelphi Real World, Bollington, United Kingdom.*

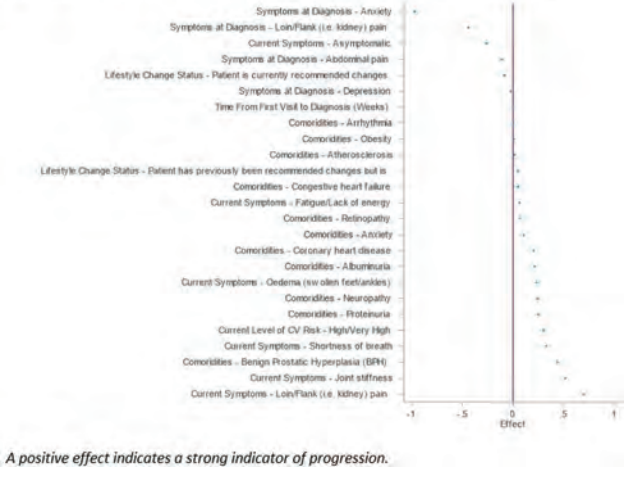
Background: Clinical decision making is difficult due to the complex heterogeneous nature of chronic kidney disease (CKD) and its variable rate of progression. We aimed to understand the key predictors of CKD progression and subsequent impact on patients.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a cross-sectional survey of physicians and patients conducted in the USA from Jan-June 2022. Physicians recorded patient demographics, disease characteristics, concomitant conditions treatment history and consultation history. Non dialysis (ND) patients reported their current and most troublesome symptoms. Elastic net regression analysis was conducted.

Results: Physicians provided data for 1525 ND patients, of these 379 also provided data. Mean [SD] age was 61.9 [13.87], 57% were male, and 55% were white. Almost half of patients had progressed (CKD stage) since diagnosis (47%). Regression analysis identified the strongest predictors of CKD progression to include: kidney pain, joint stiffness and shortness of breath, high/very high cardiovascular risk and proteinuria [Figure 1]. The strongest predictor, kidney pain, was reported as a current symptom by 10% of patients and of those, 59% reported this to be their most troublesome symptom. Of the patients experiencing joint stiffness (11%) and shortness of breath (13%), approximately a third of these patients reported them to be their most troublesome symptom(s) (31% and 35% respectively).

Conclusions: Presence of kidney pain is a strong predictor of CKD progression and in our study was shown to be most troublesome for over half of the patients experiencing it. In addition to treating the most prevalent symptoms, physicians should aim to control/ treat less prevalent symptoms to help slow progression and improve patient outcomes.

Figure 1: Elastic net regression coefficient plot to show predictors of CKD progression



A positive effect indicates a strong indicator of progression.

Changes in GFRe in a Cohort of Qom Indigenous over a 15-Year Interval

Maria Eugenia V. Bianchi,[1,2] Viviana Navarro,[2] Daniel Forlino.[2]
[1]Fundacion Renal del Nordeste Argentino, Resistencia, Argentina; [2]Universidad Nacional del Nordeste Facultad de Medicina, Corrientes, Argentina.

Background: The Qom ethnic group lives in the province of Chaco, one of the lower incomes in Argentina. In the last 15 years, they access to better living conditions. Illiteracy is 8%. The nutritional transition of poor populations goes from the double burden of malnutrition to obesity. The objective of this work is to describe the changes of eGFR by CKDEpi, and the frequency of proteinuria, obesity, HT, and DM in a cohort of the Qom ethnic group, inhabitants of suburban neighborhoods of the city of Resistencia, Chaco, Argentina, in two cross-sections (2003-2018).

Methods: A descriptive, observational study of two cross-sections was carried out in 2003 and in 2018, visiting each participant's home, and were included after signing the informed consent. Glycemia was measured by the Hexokinase Enzymatic Method, and Creatininemia, and Creatininuria by the Jaffé kinetic method. Proteinuria was classified according to the PrU/CrU index following KDigo (2012). Diabetes Mellitus (DM) by the medical report. Nutritional status according to WHO. HT according to JNC 7. GFR by CKDEpi formula. Risk Progression RR) by KDIGO risk categories.

Results: 65 people were studied. The mean age in 2003 was 33.57 ± 12.53 and 49.09 ± 12.40 years old in 2018; 38 (62.3%) were female. The eGFR in 2003 was 101.10 ± 15.39 ml/min and in 2018, 102.10 ± 15.85 ml/min; 19.7% and 23% (p= 0.02) respectively presented proteinuria. HT increased from 26.22 to 62.69%; 14.2% developed DM. Obesity increased from 26.2% to 60.6%. Low RR raised from 68.3% to 76, 66%, 10% to 21.66% moderate and high RR only 1.66% in 2018. The correlation between GFRe in 2003 and 2018 is shown in Figures 1 and 2.

Conclusions: This epidemiological study shows that eGFR tends to increase due to obesity and DM and to decrease in patients with HT in a 15 years interval.

Association of Bicarbonate Use and Incident ESKD Among US Veterans with Incident CKD

Diana Tran,[1] Prabin Shrestha,[2] Keiichi Sumida,[2] Connie Rhee,[1] Fridtjof Thomas,[2] Kamyar Kalantar-Zadeh,[1] Csaba P. Kovesdy.[2] *[1]University of California Irvine Medical Center, Orange, CA; [2]The University of Tennessee Health Science Center, Memphis, TN.*

Background: Treatment of metabolic acidosis delayed the decline of kidney function in patients with chronic kidney disease (CKD) in small clinical trials, but the effects of bicarbonate therapy on end-stage kidney disease (ESKD) in unselect populations with all stages of CKD remains unclear. We examined the association of sodium bicarbonate use with incident ESKD in a large national cohort of US Veterans.

Methods: In a cohort of 50,540 patients with incident CKD (eGFR <60 mL/min/1.73m^2), we examined the association of de novo prescription of bicarbonate containing medications with incident ESKD (defined as initiation of kidney replacement therapy). We examined associations in Cox proportional hazard models adjusted for demographics, major comorbidities, baseline eGFR, urine albumin-creatinine ratio (UACR), and use of renin angiotensin-system inhibitors.

Results: We identified 11,896 incident new bicarbonate users. Overall mean (SD) age was 65 (10) years, with 3.0% female, 15.3% Black, and 5.5% Hispanic, and baseline eGFR of 35 (11). Bicarbonate users were more likely to be male, Black, current smokers, had higher frequencies of diabetes and liver disease and lower eGFR compared to non-users. ESKD developed in 4860 patients (event rate 37.4/1000 patient years, 95% CI: 36.3-38.4). Bicarbonate use (vs. non-use) was associated with higher risk of incident ESKD in the unadjusted (HR: 8.68, 95% CI: 8.17-9.23) and in the fully adjusted model (1.48, 1.38-1.60), Table.

Conclusions: In this large national cohort of US Veterans with long follow-up time, bicarbonate use was associated with higher risk of incident ESKD. Further studies are needed to test the effects of bicarbonate replacement in patients with CKD.

Funding: NIDDK Support, Veterans Affairs Support

Table. Hazard Ratio and 95% Confidence Interval of Incident ESKD Among Bicarbonate Users vs. Non-Users

Models	HR (95% CI)	P
Model 1: Unadjusted	8.68 (8.17-9.23)	<0.0001
Model 2: Adjusted for demographics	6.48 (6.08-6.91)	<0.0001
Model 3: Adjusted for demographics and comorbidity	5.84 (5.47-6.23)	<0.0001
Model 4: Adjusted for demographics, comorbidity, and eGFR	1.93 (1.79-2.08)	<0.0001
Model 5: Adjusted for demographics, comorbidity, eGFR, UACR	1.50 (1.39-1.61)	<0.0001

Invasive Fungal Infection Associated with SGLT2 Inhibitor Use

Prathap Simhadri,[1] Pradeep Vaitla,[2] Sriram Sriperumbuduri,[2] Ujjwala Murari.[3] *[1]AdventHealth, Daytona Beach, FL; [2]The University of Mississippi Medical Center, Jackson, MS; [3]West Virginia University, Morgantown, WV.*

Introduction: Sodium-glucose co-transporter-2 inhibitors (SGLT2i) are a relatively newer class of medications approved by the U.S. Food and Drug Administration (FDA) in 2013 to treat Type 2 Diabetes Mellitus. Over the last few years, the indications for SGLT2i have been expanded to decrease the risk of kidney disease and cardiovascular disease. SGLT2 inhibitors are associated with an increased risk of euglycemic diabetic ketoacidosis, urinary tract infections, and genital mycotic infections. We present a case of candida fungemia and renal abscess in a patient on an SGLT2 inhibitor.

Case Description: A 75-year-old white male with a history of hypertension, obesity, CKD stage IIIB with baseline creatinine(Cr) of 1.6 mg/dl, and BPH presented to the hospital with fever and lethargy. He had been on valsartan and empagliflozin over 2 years. He underwent a biopsy of the prostatic lesion a week before the presentation. He did not have exposure to antibiotics prior to presentation. Urinalysis showed the presence of glucose and WBC with fungal elements on microscopy. Computed tomography of the abdomen showed fluid in the superior pole of the left kidney with surrounding inflammatory changes concerning renal abscess. There were inflammatory changes in the left renal collecting system with thickening of the urothelium and bladder wall. He underwent percutaneous abscess drainage; blood cultures, abscess fluid cultures, and urine cultures grew Candida tropicalis. He was initially given intravenous fluconazole, later transitioned to oral fluconazole therapy for a total of 6 wks. The patient was discharged home in stable condition.

Discussion: SGLT2 inhibitors are being widely prescribed due to their beneficial effects on kidney and cardiovascular outcomes among the diabetic and non-diabetic populations. SGLT2 inhibitors, through the induction of renal glycosuria, create a conducive environment for the proliferation and colonization of candida in the genital tract. SGLT-2 inhibitors related to fungal infections are common, but most are limited and present as vulvovaginitis in women and balanitis in men. However, invasive fungal infections should be considered in patients with complex urinary anatomy and undergoing urological surgeries. It is reasonable to stop SGLT-2 inhibitors prior to elective urological surgery to minimize the risk of invasive fungal infections.

PUB439

Effect of Dapagliflozin on eGFR Slope in Nondiabetic CKD Patients

Shunsuke Kitamura, Marumi Yamamoto, Yoshiyuki Miura, Go Okanishi, Kosuke Tansho, Maiko Kokubu, Masaru Matsui. *Nara-ken Sogo Iryo Center, Nara, Japan.*

Background: Treatment with sodium-glucose co-transporter-2 inhibitors (SGLT2i) has a great impact of renal protection showing a significant improvement in eGFR decline in patients with CKD. However, the timing of eGFR crossing between patients receiving placebo and SGLT2i is inconsistent. In this study, we aimed to determine factors associated with eGFR slope one year after the initiation of SGLT2i in non-diabetic CKD patients.

Methods: We conducted a cohort study on 260 non-diabetic CKD patients in whom dapagliflozin was initiated at 5 or 10 mg daily from August 2021 and July 2022. Among them, one-year follow up was completed in 138 patients. The total slope (TS) was estimated by using two measurements of eGFR levels at the baseline and one-year follow-up, while the long-term (LS) slope was calculated using two eGFR levels at one month after the first dose of dapagliflozin and one-year follow-up. Multivariate linear regression was used to identify characteristics with an independent association with TS and LS. The baseline slope (BS) before dapagliflozin initiation and TS and LS was compared using-paired-t-test in CKD patients according to characteristics, respectively.

Results: The mean age was 62±13 years and 105 (40%) were male. The baseline eGFR were 43±15 mL/min/1.73m^2 and the proteinuria was 0.61±0.94 g/gCre. The underlying kidney diseases included glomerulonephritis in 109 (42%) patients and hypertensive nephrosclerosis in 106 (41%). The administration of renin-angiotensin blocker and 5mg of dapagliflozin was observed in 170 (65%) patients and 109 (42%). BS was -1.67 mL/min/1.73m^2/yr, while TS and LS was -1.45 mL/min/1.73m^2/yr (p=0.56 vs. BS), and -0.4 mL/min/1.73m^2/yr (p=0.02 vs. BS, p=0.003 vs.TS), respectively. In multivariate analysis, TS was significantly associated with BS, while an independent association of LS with overweight was found. TS was significantly improved compared with BS in patients with G4-5 and BS < -3 mL/min/1.73m^2/yr. We found significant improvements in LS compared with BS were observed in patients with nephrosclerosis, less proteinuria, taking renin-angiotensin blockers and 10mg of dapagliflozin as well as G4-5 and fast eGFR decline.

Conclusions: In non-diabetic CKD patients dapagliflozin may have the potential to significantly improve eGFR slope in high CKD risk category, possibly within a relatively short period.

PUB440

Extrarenal Pelvis: Benign Anatomical Variation Mimicking Hydronephrosis

Catherine T. Pham,[1,2] Arianna S. Moss,[1,2] Ekamol Tantisattamo.[1,3] *[1]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]University of California Irvine School of Medicine, Irvine, CA; [3]Nephrology Section, Department of Medicine, Tibor Rubin Veterans Affairs Medical Center, Veterans Affairs Long Beach Healthcare System, Long Beach, CA.*

Introduction: Extrarenal pelvis is a normal anatomical variant in which the renal pelvis is outside of the renal hilum without affecting kidney function. It can be challenging to differentiate from hydronephrosis. We report a case of a woman with stable kidney function who was referred for an incidental kidney imaging. A kidney ultrasound confirmed the diagnosis of extrarenal pelvis.

Case Description: A 67-year-old woman with non-proteinuric stage 2 chronic kidney disease presumably secondary to hypertension presented with chronic low back pain after a motor vehicle accident 1 year ago. She denied lower urinary tract symptoms, bladder or bowel incontinence, or focal neurological deficits. A pelvic CT scan incidentally showed right extrarenal pelvises without calculi or hydronephrosis (Figures 1A and 1B). A kidney ultrasound revealed the right kidney with normal echogenicity and contour and an extrarenal pelvis measuring up to 1.5 cm without hydronephrosis, focal kidney mass or shadowing stones (Figure 1C). The patient remains having no symptoms and signs of urinary tract obstruction and follow-up serum creatinine has been stable at 0.7 – 0.9 mg/dL.

Discussion: While imaging may show similar findings between the extrarenal pelvis and hydronephrosis, which appears as interconnected areas with branching of decreased echogenicity consistent with fluid, normal or stable kidney function without evidence of obstructive uropathy clinically suggests extrarenal pelvis. Reassuring patients with extrarenal pelvis that their condition is benign and does not require therapy is imperative.

PUB441

Predictability of GFR with Cystatin C: A Case Report

Mansoor Ahmed, Rula A. Abdulrahman. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Chronic Kidney Disease (CKD) is a common single entity or frequent comorbid in the United States, affecting 1 in every 7 persons, leading to multiple cardiovascular and metabolic complications.[1]CKD is defined by structural or functional abnormalities of the kidney, with or without decreased GFR of <60 mL/min/1.73m2 for ≥3 months, with or without kidney damage.[2] Measurement of GFR in clinical practice can be complex, time consuming, and cumbersome to perform. Traditionally, GFR is measured using creatinine based equations, CKD-EPI, MDRD, Cockroft-Gaulet equations. However, confirmation of creatinine-based estimated GFRs (eGFR) must take into account subjects who have high muscle mass, taking creatine supplements, low muscle mass, vegan diet, liver disease, extreme weakness.[3]

Case Description: We report a 31 year old Caucasian muscular male, with no established primary care, who was referred in an ambulatory setting for elevated creatinine thought to be CKD. Upon evaluation, he has good muscle mass, reporting muscle pains from workout, uses muscle building supplements. His family history is significant for breast cancer in mother, no kidney diseases or nephrolithiasis. His surgical history is significant for tonsillectomy at the age of 22 years. His initial labs show creatinine (Cr) of 1.45, BUN 26, eGFR 66ml/min/1.73m2, electrolytes within range. In view of elevated Cr, patient was advised to stop taking Creatine supplements. Repeat labs in 2 weeks continued to demonstrate elevated Cr to 1.54, with preserved GFR. Renal US and UA insignificant, HbA1c 5.4%, neg HIV, Hep: B/C neg. Patient was advised to discontinue all nutritional supplements. Repeat labs in 6 months, showed Cr of 1.48, BUN 21, GFR of 64min/ml/1.73m2, urine protein/creatinine ratio 0.07, Hgb 13.2. In view of this, Cystatin C was obtained with intent to follow up with renal biopsy. Results for Cystatin C 0.7, eGFR by Cystatin C 126ml/min/1.73m2, sCr 1.34.

Discussion: Cystatin C is a useful clinical biomarker to estimate GFR. It has been found to provide a more accurate estimate of GFR in certain patient populations, unlike Creatinine which has limitations of age, gender, body muscle mass, and ethnicity. In our case, Cr was elevated and eGFR was decreased, that led to misdiagnosis of CKD. Using Cystatin C established more accurate GFR and ruled out CKD. We suggest the use of cystatin C into diagnostic criteria and treatment guidelines for CKD.

PUB442

Ultrasound Measured Renal Sinus Fat, Parenchymal Thickness, Interstitial Fibrosis, and Their Association with Renal Function

Ana I. Stark, Jafar Alsaid, Mu'ath N. Abdeen. *Ochsner Medical Center, New Orleans, LA.*

Background: Renal ultrasound is valuable for nephrologists in clinical practice to determine the proper management. Measuring renal sinus fat and renal parenchymal thickness was proven to have some clinical implications. In this study we wanted to determine the correlation between ultrasound measured renal sinus fat length, parenchymal thickness and interstitial fibrosis with renal function.

Methods: This is a retrospective cross-sectional study for patients biopsied by the Interventional Nephrology division in Ochsner Medical Center over 2 years 2021-2023. Patients without ultrasound reports were excluded. The demographic factors were recorded from the electronic files. The eGFR was calculated by CKDMB equation within the time closest to the biopsy. The sinus fat length was measured on longitudinal sagittal US image. The total renal length was measured on the same image. The renal parenchymal thickness was measured by subtracting the longitudinal sagittal length of the sinus fat from the total kidney length. The percentage of sinus fat length was measured by dividing the length of sinus fat over the total renal length using the ipsilateral site of the biopsy. SPSS 25 was utilized for the descriptive statistics. Two tails Spearman correlation was used to calculate the significant correlation. P< 0.01 was needed to reject the null hypothesis.

Results: Total patients included were 52. Mean age: 50 years. (SD 17.5, SE 2.27). Male gender 45%. Mean BMI 29.3 kg/m2 (SD 7.2, SE 0.9) DM was present in 23% of the patients. HTN was present in 55% of the patients. Mean Interstitial fibrosis was 20% Mean S. Cr. 2.3mg/dl (SD 2.2, SE 0.28) Mean eGFR: 42ml/min. (SD 19.3, SE 2.5)

Conclusions: There was a significant correlation between ultrasound measured sinus fat length percentage and parenchymal thickness with renal function. Sinus fat and parenchymal thickness were not associated with age, gender, BMI, DM or HTN. Interstitial fibrosis was significantly associated with S.Creatinine and eGFR.

Association of renal Sinus fat ratio, parenchymal thickness and interstitial fibrosis with renal function

Independent variables	S. Creatinine correlation coefficient (p value)	eGFR correlation coefficient (p value)
Sinus fat ratio	-0.39 (0.004)	0.34 (0.01)
Parenchymal thickness	0.38 (0.005)	-0.31(0.025)
Interstitial fibrosis	0.5 (<0.0001)	-0.48 (<0.0001)

PUB443

Is the Predicted Skin-to-Kidney Distance by Analytical Method Useful? A Correlation and Association with Ultrasound-Guided Percutaneous Kidney Biopsy

Brenda Cortez,[1] Omar H. Sanchez Vazquez,[2] Alejandro Garcia Rivera,[2] Hirepan Armenta,[1] Bernardo Moguel.[1] Interventional Nephrologists.
[1]*Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico;* [2]*Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico.*

Background: Approach techniques and the use of a distance prediction formula (DPF) have been created, using weight and height to estimate the depth of the skin-kidney distance (SKD) in percutaneous renal biopsy (PRB)* ultrasound guided. Its validation and usefulness are still an opportunity area.

Methods: Our objective is to correlate SKD derived by DPF in native PRB compared to real-time ultrasound stratified by body mass index (BMI) categories and evaluate its usefulness and sample quality. This is a cross sectional study spawning data from 2018-2022 in Interventional Nephrology Service of the National Institute of Cardiology Dr. Ignacio Chávez. Sampling was performed in real time guided ultrasound. DPF= (Body weight [hectograms]/height [centimeters])–0.5 in all cases. Pearson analysis was made and further stratified between BMI categories and by type of biopsy approach. Dispersion analysis was made by Bland-Altman plots at 1.96SD. Binary logistic regression models were fitted to evaluate the association between SKD and the quality of sample.

Results: 300 of 501 PRB were analyzed. The mean BMI was 25.7 kg/m². 71% were performed with transverse approach. 45.7% were classified as normal-weight, 34% overweight and 20.3% obese. The mean SKD measured by ultrasound was 4.3 (+/- 0.6) cm and by DPF of 3.61 cm (+/-0.42), deriving a correlation of 0.42 (95% CI:0.28-0.55, p<0.001). After stratification, subjects with overweight and obesity had a lower correlation and higher variability compared to subjects with normal weight (Fig. 1). Finally, SKD was not associated with the sample quality (OR:1.13, 95% IC: 0.87-1.47, p=0.36).

Conclusions: The formula has a moderate correlation in subjects with normal weight, but not with overweight and obesity. There is no association between the depth, sample quality and complications, hence, its further usefulness must be evaluated for other outcome.

Funding: Government Support - Non-U.S.

Reducing Hospital Admissions for Cardiorenal Syndrome Using Lung Ultrasound-Guided Volume Assessment in the Clinic

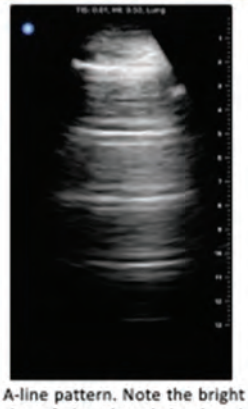
Chavely Valdes Sanchez, Mary Sifain, Margarita D. Almeida, Christopher D. Naranjo, Zachary Kornblum, Marco A. Ladino Avellaneda. University of Miami/Miami VAMC Fellowship Program. *University of Miami School of Medicine, Miami, FL.*

Background: Point-of-care ultrasound is used at the bedside to integrate the clinical assessment of patients' volume status. Volume assessment is an important clinical tool, as volume overload is a leading cause of admission and readmission. There is increased risk of mortality following each admission. Lung Ultrasound has been used across many specialties, including Cardiology, Emergency Medicine, Critical Care, and Nephrology. Volume status is a quintessential part of the physical exam, especially for those with Cardiorenal Syndrome. It is important that specialties such as Nephrology use all the available tools for volume assessment, including point-of-care ultrasound.

Methods: The use of point-of-care lung ultrasound can help the clinician assess the patient's volume status and adjust diuretic therapy in the clinic. We evaluated a total of ten patients with Cardiorenal Syndrome. Their volume status was assessed using lung ultrasound. Oral diuretic dose and frequency were adjusted according to the findings on physical exam and on the lung ultrasound.

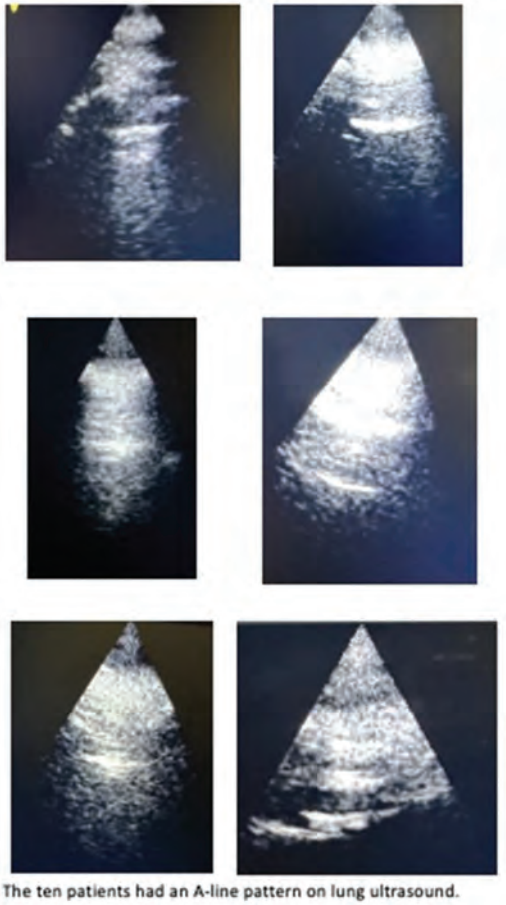
Results: The ten patients had an A-line pattern on lung ultrasound. Three patients had mild edema of the lower extremities and no changes of diuretic dose. The 10 patients continue to be euvolemic without admission to the hospital.

Conclusions: Use of Lung ultrasound in the Nephrology clinic allowed quantification of pulmonary congestion. This may identify the patients with Cardiorenal Syndrome who respond well to diuretic intensification, help them maintain euvolemia, and avoid admission.



Lung ultrasound A-line pattern. Note the bright horizontal lines at integer multiples of the pleural depth, which diminish in intensity with increasing depth.

Lung ultrasound B-lines. Note the hyperechoic vertical lines extending from the pleural line, radiating to the edge of the ultrasound field.



The ten patients had an A-line pattern on lung ultrasound.

Assessing Hospice Referral Quality and Length of Stay in Renal Patients at the Iowa City VA

Melissa L. Swee,[1,2] Qianyi Shi,[1] Mary V. Sarrazin,[1,2] Benjamin R. Griffin,[1] Meenakshi Sambharia,[1] Masaaki Yamada,[1,2] Diana I. Jalal.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA.*

Background: Quality assessment of hospice referrals is crucial, but assessment within the Veterans' Health Administration (VHA) and its concurrent care (CC) coverage is understudied. This study evaluates the quality of hospice care at the Iowa City VA (ICVA) in nephrology patients, including LOS, referral patterns, and the effectiveness of a flagging system for hospice enrollment.

Methods: Our objectives were to implement a standardized system for tracking hospice LOS through Electronic Health Records (EHR) flagging, assess hospice LOS, identify gaps in LOS and referral patterns, and evaluate the accuracy of flag placement for hospice enrollment. We identified ICVA patients who died following hospice referral between October 2018 and July 2021 using an internal database. Focused chart reviews provided LOS, hospice diagnosis, referral source, and time lag between hospice enrollment and flag placement. Additional chart review focused on patients with LOS <7 days to identify potential gaps in care. Median LOS was compared using Kruskal-Wallis, and Chi2 analysis assessed enrollment rates across groups.

Results: Analysis included 661 patients. Common hospice diagnoses were cancer (47.4%), cardiac disease (13.3%), and respiratory illness (13.0%). Among CC patients, cancer was the predominant diagnosis (80.4%). The median hospice LOS was 27.5 days (range: 0-912), while CC LOS was 62 days (range: 4-721). The mean gap between hospice enrollment and flag placement was 3.8 days, with a median discrepancy of 1 day and mode of 0 days (range: 0-514 days). Hospice LOS did not significantly vary by diagnosis, year, or referral source, and CC LOS did not vary by diagnosis. Renal disease patients were underrepresented in both groups and had comparatively shorter median LOS (14 days). Approximately 20% of patients had a short LOS (7 days or less).

Conclusions: Manual flagging of patient charts provides a reliable method to track hospice enrollment date and LOS, with potential implications for the VHA. Our study identified areas for improvement, particularly in the care of nephrology patients with renal disease and those with short LOS. Implementing interventions to address these findings can enhance end-of-life care in nephrology within the ICVA.

PUB446

Molecular and Metabolic Alterations of Lipoproteins and Fatty Acids in CKD

Heidi Noels,[1] Joachim Jankowski.[1,2] *[1]Universitatsklinikum Aachen, Aachen, Germany; [2]Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: Chronic kidney disease (CKD) has a significant impact on lipid and lipoprotein metabolism and homeostasis. These modifications play a crucial role in promoting, modulating, and accelerating CKD and secondary cardiovascular disease (CVD). The changes in lipid and lipoprotein profile encompass variations in protein composition, incorporation of small molecules, and post-translational modifications. Metabolic changes can induce mitochondrial dysfunction and cellular damage, contributing not only to cardiovascular complications but also to the progression of kidney damage.

Methods: An extensive analysis of available literature regarding the alterations in lipid and lipoprotein metabolism in patients with chronic kidney disease was carried out. Relevant studies, research articles, and clinical data were identified through comprehensive searches of databases. The selected information focuses on the modifications in lipid and lipoprotein profiles, including changes in concentration and molecular structure, and their implications for the pathophysiology of CKD and the development of cardiovascular disease.

Results: Lipoprotein abnormalities, such as elevated triglyceride-rich lipoproteins, LDL, and altered HDL, are not only associated with changes in concentration but also exhibit structural changes that impact their biological activity. These modifications can initiate pro-inflammatory and pro-atherogenic processes and induce oxidative stress. Additionally, patients with CKD commonly experience disturbances in serum fatty acid levels, leading to disruptions in fatty acid metabolism, mitochondrial dysfunction, and cellular damage. These lipid and lipoprotein abnormalities interact with the inflammatory and oxidative environment in CKD, further exacerbating cardiovascular risk.

Conclusions: The competing risk of non-atherosclerotic cardiovascular death in individuals with declining kidney function poses additional challenges for therapeutic interventions. Understanding the relationships between lipid and lipoprotein modifications, kidney dysfunction, and the genesis and/or progression of cardiovascular disease in patients with CKD will provide valuable insights for the development of effective therapeutic strategies.

Alteration of the Gut Microbiota in CKD

Shruti Bhargava,[1] Joachim Jankowski.[1,2] *[1]Universitatsklinikum Aachen, Aachen, Germany; [2]Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: The gut microbiota, consisting of trillions of microorganisms, plays crucial roles in various physiological processes. However, it also contributes to the progression of chronic kidney disease (CKD).

Methods: The information presented in this article is based on existing literature related to gut microbiota in patients with CKD. Relevant studies, research articles, and clinical data were collected from various databases and sources. The selected information focuses on the pathophysiology, clinical consequences, and underlying mechanisms of gut microbiota in CKD.

Results: The human gut microbiome comprises bacterial species from major phyla, including Firmicutes, Bacteroidetes, Actinobacteria, Proteobacteria, and Verrucomicrobia. Changes in the composition of these phyla result in an imbalance between beneficial and pathogenic bacteria, exacerbating CKD. Additionally, CKD-associated modifications of the gut microbiome lead to metabolic changes and the accumulation of uremic metabolites, such as amines, indoles, and phenols. These metabolites negatively affect renal function and contribute to comorbidities like atherosclerosis and cardiovascular diseases. Uremic toxins were categorized based on known toxicity and experimental evidence, playing a significant role in CKD. Small water-soluble compounds, protein-bound compounds, and middle molecules are representative uremic toxins, with their production influenced by the gut microbiota. Gut-derived uremic metabolites damage the intestinal epithelial barrier, increase gut permeability, and facilitate the translocation of bacteria and endotoxins into the bloodstream. This leads to endotoxemia, inflammation, and further acceleration of CKD progression.

Conclusions: While the importance of the gut microbiome in CKD pathophysiology is recognized, the underlying mechanisms remain incompletely understood. An overview of the current research on CKD, the gut microbiota, alterations in the microbiome, production of uremic toxins, and degradation of the gut epithelial barrier would lead to identification of novel theapeutic targets.

PUB448

Cortical Iron Deposition Is Associated with Kidney Fibrosis and Can Be Assessed by Magnetic Resonance Imaging

Carlos Couceiro Monteagudo,[1,2] Diego Sandoval Rodriguez,[1] Isabel Puig Povedano,[1] Sergi Codina Sanchez,[1,2] Anna Manonelles,[1,2] Mate Maus,[3] Manuel Serrano,[4] Maria Quero,[1,2] Anna Sola,[2] Josep M. Cruzado.[1,2] *[1]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [2]Institut d'Investigacio Biomedica de Bellvitge, Barcelona, Spain; [3]Vall d'Hebron Institut d'Oncologia, Barcelona, Spain; [4]Institut de Recerca Biomedica, Barcelona, Spain.*

Background: Fibrosis is responsible for the loss of kidney function as a result of several insults, such as ischemia-reperfusion injury or hyperfiltration. This process can continue even after cessation of the primary insult, as documented in acute kidney injury to chronic kidney disease. Recently, we discovered that iron accumulation is a hallmark of fibrotic diseases, and its deposition accompanies the progression of the disease.

Methods: In a cohort of patients with diabetic kidney disease (DKD), we studied iron deposits through Pearls staining, and its correlation with histological parameters. In a second time, we evaluated prospectively iron deposits through Magnetic Resonance Image (MRI) in a cohort of kidney transplant (KT) recipients who underwent a kidney biopsy and its association with IFTA (interstitial fibrosis and tubular atrophy).

Results: We classified DKD biopsies according to iron deposition (Table 1). The group with positive staining significantly exhibited more IFTA. In the prospective study, we collected data from 15 KT recipients. Mean age, time from KT to biopsy and eGFR were respectively 58.3 years old, 4.3 years and 44.4 ml/min/1.73m2. We found that patients with high IFTA score presented with significantly higher deposits (p=0.005), than patients with low IFTA score. We also found positive and significant correlation between iron deposits and IFTA (r=0.7537, p=0.0012).

Conclusions: Iron deposits are associated with fibrosis, and its detection through MRI could be considered a non-invasive marker.

Table 1. Analysis considering absence (Negative) or presence (Positive) iron staining in diabetic nephropathy biopsies

Variables	Negative N=10	Positive N=16	P value
Gender (Male/Female)	9/1	11/5	0.44
Age (years, SD)	66.9 (5.5)	61.4 (11.1)	0.16

Not All Controls Are Made Equal: Comparison of Single-Cell Gene Expression in Human Kidney Reference Samples

Rajasree Menon,[1,2] Edgar A. Otto,[1,2] Jeffrey B. Hodgin,[1,2] Abhijit S. Naik,[1,2] E. Steve Woodle,[7] John R. Sedor,[3] Sylvia E. Rosas,[4] Sushrut S. Waikar,[5] Markus Bitzer,[1,2] Petter Bjornstad,[6] Matthias Kretzler.[1,2] KPMP. *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Cleveland Clinic, Cleveland, OH; [4]Joslin Diabetes and Endocrinology Research Center, Boston, MA; [5]Boston University Medical Campus, Boston, MA; [6]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [7]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Defining molecular mechanism of kidney disease relies on comparison to healthy reference tissue. With the rapid development of molecular analysis tools understanding advantages and limitations of the different reference tissue sources is critical. Here, we compared single-cell gene expression data from four different reference tissue sources including percutaneous kidney biopsies in healthy volunteers (HV), unaffected parts of tumor-nephrectomies (TN) and two sources of living kidney donor biopsies (LD). Diabetic kidney disease data (DKD) (KPMP) was included as a disease comparator.

Methods: Kidney tissue was procured as published (PMC8330551) with institutional approval and after informed consent of study participants. Single cell data from 10 HV, 16 TN, 18 LD, 27 DKD samples were generated. Integration of single cell data (10x Chromium) from all sample groups was done using reciprocal principal component analysis in Seurat R package. For comparative analyses, each group was down sampled to 15000 cells.

Results: The integrated dataset was annotated to 19 cell types which encompassed major kidney cell types. An adaptive/maladaptive proximal cell state based on markers from the published KPMP kidney atlas study had low representation in HV compared to other groups. Similarly, low expression of injury markers including NGAL and KIM1 and low representation of immune cell types were observed in HV. Principal component analysis clustered HV away from the other reference groups. 155 genes that were common among the over-expressed genes in HV compared to other groups with ion import across plasma membrane as top enriched term. TN had the greatest number of uniquely differentially expressed genes compared to HV with WNT signaling as a top enriched term. mRNA processing and hypoxia are enriched for the few uniquely differentially expressed genes in LD vs HV.

Conclusions: Immune and maladaptive epithelial cell proportion in HV group was lower than the other groups. However, each reference sample group had unique features. These differences could be explained when the transcript data is integrated with clinical, demographic and pathologic parameters; these integrated analyses are ongoing.

Apolipoprotein C3-Rich Low-Density Lipoprotein (LDL) Induces Human Aortic Endothelial Cells Senescence via FBXO31/p53/p21

Jie S. Wang,[1,2] Ping H. Tsai,[1] Kuo F. Tseng,[3] Ming-Yi Shen.[3] MYS Lab. *[1]China Medical University Graduate Institute of Biomedical Sciences, Taichung City, Taiwan; [2]China Medical University Hospital, Taichung, Taiwan; [3]China Medical University, Taichung, Taiwan.*

Background: Apolipoprotein C3 (ApoC3) delays the catabolism of triglyceride-rich particles. However, the effects of ApoC3 on uremic dyslipidemia progression is unknown.

Methods: Plasma samples were obtained from diabetic kidney disease (DKD) patients recruited at our outpatient clinic. Low-density lipoprotein (LDL) was separated from other lipids by sequential potassium bromide density centrifugation. ApoC3-rich low-density lipoprotein (AC3RL) was isolated from plasma LDL with the affinity-purified method.

Results: AC3RL induced human aortic endothelial cells (HAEC) senescence in a dose-dependent manner. Reactive oxygen species (ROS) was involved in AC3RL-Induced HAEC senescence. The level of FBXO31, p53 and p21 were markedly increased in AC3RL-induced HAECs. Moreover, silencing FBXO31 attenuated AC3RL-induced DNA damage and reduced cellular senescence.

Conclusions: Inhibiting FBXO31 may protect endothelial damage and arrest the progression of DKD by linking AC3RL elevation to aging and uremic dyslipidemia.

Role of Cell-Extracellular Matrix (ECM) Interactions for Renal Tubular Epithelial Cell Phenotypes in the Context of Progressive CKD

Annika Merz,[1,2] Manuel Rogg,[1] Andrea Paolini,[3] Gerd Walz,[3] Christoph Schell.[1] Schell Lab. *[1]Universitatsklinikum Freiburg Institut fur Klinische Pathologie, Freiburg, Germany; [2]Speeman Graduate School of Biology and Medicine, Freiburg, Germany; [3]Universitatsklinikum Freiburg Abteilung Innere Medizin IV Nephrologie und Allgemeinmedizin, Freiburg, Germany*.

Background: Chronic kidney disease (CKD) is mainly defined by interstitial fibrosis of the renal parenchyma and progressive atrophy of proximal tubules (PT). The latter is characterized by pronounced thickening and multilamellation of the tubular basement membrane, whereas fibrosis is promoted by accumulation of extracellular matrix (ECM) translating into increased matrix rigidity. The role of mechanotransduction via integrin adhesion complexes (IAC) as well as the corresponding signaling programs activated in this context remain elusive. Here, we aimed to elucidate the functional role of the ILK-Pinch-Parvin (IPP) complex as an essential part of the IAC in PT damage response and CKD.

Methods: Morphometric assessment of ischaemia-reperfusion injury (IRI) mouse models was performed. Transcriptome studies of human proximal tubular epithelial cells (hRPTECs) under pro-fibrotic conditions were analyzed. CRISPR/Cas9 genome editing was employed to generate knockout cell lines of the IPP complex (ILK, PARVA and PARVA/PARVB double KO), complemented by functional assays.

Results: TGFb treatment (resembling pro-fibrotic conditions) resulted in a partial epithelial-to-mesenchymal transition (pEMT) state of hRPTECs. Transcriptome analysis demonstrated an altered regulation of several matrisome and adhesome genes, including members of the IPP complex. Similar alterations were observed in PTs of IRI mice. Further characterization using IPP-KO cell lines revealed an altered cytoskeleton, cell morphology and total number of IACs, as well as an altered distribution of the latter. Interestingly, PARVA/B double KOs lacked the ability to form a proper cytoskeleton, resulting in a significant reduction in cell area and IACs. Further genetic perturbation studies demonstrated the strong interdependence of individual IPP-complex members for stabilization and regulation of IACs. IPP-KO cell lines failed to form a multilayered and interconnected extracellular matrix, demonstrating a key role of IPP proteins in mechanosignaling.

Conclusions: We have established a simplified model to investigate processes of pEMT in hRPTECs resembling hallmark features of tubular remodeling in CKD. In vivo, transcriptome and functional data indicate a central role of the IPP-complex in orchestrating cell-matrix interactions as an underlying theme of tubular atrophy.

New Targets for Cardiovascular Disease (CVD) in CKD: Proteomic Analysis of Indoxyl Sulfate-Treated Endothelial Cells and Extracellular Vesicles (EVs)

Andrea Figuer Rubio,[1] Fátima Milhano dos Santos,[2] Gemma Valera Arévalo,[3] Sergio Ciordia,[2] María Del Mar Rodríguez San Pedro,[3] Guillermo Bodega,[4] Enrique Morales,[5] Rafael Ramirez,[1] Julia Carracedo,[3] Matilde Alique.[1] *[1]Departamento de Biología de Sistemas; Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Madrid, Spain; [2]Laboratorio de Proteómica Funcional, Centro Nacional de Biotecnología (CNB-CSIC), Campus de Cantoblanco, Madrid, Spain; [3]Departamento de Genética, Fisiología y Microbiología, Facultad de Ciencias Biológicas, Universidad Complutense de Madrid, Madrid, Spain; [4]Departamento de Biomedicina y Biotecnología, Universidad de Alcalá, Madrid, Spain; [5]Departamento de Nefrología del Hospital Universitario 12 de Octubre, Instituto de Investigación i+12, Madrid, Spain*.

Background: CKD is characterized by an accumulation of uremic toxins that promote endothelial damage, generating CVD. The proteome of damaged endothelial cells and the release of extracellular vesicles (EVs), that can function as mediators and/or biomarkers, have been studied to clarify the mechanisms underlying the pathogenesis of cardiovascular complications in kidney disease and identify potential diagnostic and therapeutic targets. Thus, the study aimed to describe changes in the levels of proteins in both endothelial cells and their EVs treated with indoxyl sulfate (IS).

Methods: HUVEC were cultured in two different conditions: control (n=5) and IS-treated (250 μM, 24 h; n=5), and EVs released by the cells were isolated. Proteins from cells and EVs were isolated and analyzed using mass spectrometry to identify and quantify their protein patterns.

Results: In the proteomic analysis of cells, a total of 5871 proteins (5836 groups) were identified, while 3614 proteins (3546 groups) were identified in EVs (FDR<1%). Among these proteins, 145 showed significant differential expression (75 downregulated, 70 upregulated) and 141 differentially expressed in EVs (77 downregulated, 64 upregulated in IS-treated cells vs. control). In addition, reduced levels of proteins involved in replication and mitotic error prevention (MCM2, TACC3), and translation initiation factors (EIF3H, EIF3F, EIF4E) were detected in cells. These changes were accompanied by increased expression of transcriptional inhibitors (ING5, CTCF), caspase 3 and the downregulation of serpin-B3 (apoptosis inhibitor). Additionally, a reduction in extracellular matrix proteins (collagens, ECM1, fibronectin, perlecan) was observed in EVs and an MMP1 increase. Furthermore, elevated levels of complement components (C5, CFI), bactericidal protein LYZ, chemotactic protein S100A7, adhesion molecule ICAM-1, and immune activation marker CALML5 were detected.

Conclusions: The study suggests that IS induces cellular endothelial damage and inhibits proliferation. The results show that IS-treated EVs have a proinflammatory effect that may trigger the activation of immune cells. These newly identified molecules are promising as potential diagnostic markers and therapeutic targets for CKD.

PUB453

IL-33-Mediated Mast Cell Activation Promotes Renal Fibrosis by Regulating the Phenotype of Neutrophil

Haotian Wei, Yanyan Liu, Gang Xu. *Tongii Hospital of Tongii Medical College, Huazhong University of Science and Technology, Wuhan, China*.

Background: To investigate the mechanism that IL-33 activates mast cell and promotes its degranulation, which then recruits and regulates the phenotype of neutrophil in the development of renal fibrosis.

Methods: Analyzed the correlation between the density of infiltrating MC in kidney and renal fibrosis. mIL-33, anti-ST2 antibody and Rapamycin were used to clarify the impact of autophagy on mast cell activation and degranulation. Then, the maturation and phenotypic changes of neutrophils were detected. Finally, using MC knockout mice were transfused with mast cells inhibited of autophagy and mIL-33 to detect the maturation and phenotypic changes of neutrophil after kidney injury.

Results: (1)The degree of mast cell infiltration in renal biopsy specimen of IgA nephropathy patients was positively correlated with the degree of renal interstitial fibrosis. Knockout mast cell eliminated UUO-induced renal fibrosis and neutrophil infiltration, while reconstituted with mast cells aggravated UUO-induced renal fibrosis and neutrophil infiltration. (2)Neutrophil infiltration was correlated with the progression of renal fibrosis, and gradually differentiates into pro-inflammatory phenotype. Knocking down neutrophil can significantly inhibit the progression of renal fibrosis. (3)In the early stage of renal injury, renal tubular epithelial cells secreted IL-33, which activates mast cells through its receptor ST2, inhibited autophagy and promoted degranulation, then secreted CXCL1. (4)Both mast cells and CXCL1 can promote neutrophil maturation and differentiate into pro-inflammatory phenotype in vitro. In vivo, reconstituted with mast cells inhibited of autophagy can reduce neutrophil infiltration and alleviate the differentiation. Recombinant IL-33 can enhance neutrophil infiltration in kidney and promote the differentiation of neutrophil into pro-inflammatory phenotype.

Conclusions: In the early stage of renal injury, the injured renal tubular epithelial cells could secrete IL-33, activated mast cells by inhibiting autophagy and then promoted degranulation, which recruited neutrophil infiltration in the kidney and gradually differentiated into pro-inflammatory phenotype. Together, these effects accelerated the process of renal fibrosis.

Protective Role of Tulsi (Holy Basil) Extract in Renal Epithelial Wound Repair

Onyebuchi Ukaeje,[1,2] Bidhan C. Bandyopadhyay.[2] *[1]Washington DC VA Medical Center, Washington, DC; [2]Calcium Signaling Lab, DC VA Medical Center, Washington, DC.*

Background: Wound/injury from a resultant reactive oxygen species (ROS) can ultimately leads to chronic kidney disease (CKD). ROS productions are much higher in proximal tubular (PT) cells, which makes them vulnerable to oxidative damage, thus predispose to CKD. We tested the effect of Tulsi Chai (TC) and its ability to protect renal epithelial cells from the ROS in a wound-healing model. We induced CKD-like condition in our model by introducing calcium phosphate (CaP) crystals into PT cells in a scratch wound.

Methods: Hydrothermally extracted Tulsi extracts used as TC to investigate its wound healing property towards mechanical injury, cell survival and reversal of oxidative stress on human proximal tubular kidney-2 (HK-2) cells. H_2O_2 (crude) and CaP crystals (pathogenic) were used as ROS-inducers on the cells to impose different treatment (dose and concentrations) regiments. Cell survival was determined by Trypan blue exclusion assay, cytoplasmic reactive oxygen species (ROS) level was determined by H_2O_2 release assay. Apoptosis was examined using AnnexinV and DAPI staining whereas necrosis was identified by propidium iodide staining and Lactate Dehydrogenase (LDH) release. Wound healing assay and the molecular mechanism for wound healing were evaluated by gene expression and phosphorylation.

Results: Pretreatment of TC in HK2 cells caused a significant cell-survival and reduction of ROS generation in a concentration dependent manner. Reversal of H_2O_2-induced HK2 cell death and cytotoxicity by cell viability and extracellular LDH release indicate the protective role of TC. Wound closure and the rate of repair of wound by TC were found to be directly proportional to the amount of TC pretreatment. CaP-induced apoptosis and necrosis as investigated with the HK-2 cells showed reduction in apoptotic, necrotic and cell wall fragmentation for cells preconditioned with TC in a dose dependent manner. TC mitigated the ROS-induced phosphorylation of phospho-P38 (pP38) in our CaP-induced wound closer model.

Conclusions: Our study shows that TC has the ability to remediate both mechanical and ROS induced wounds on renal tubular cells, hence, may have the potential for natural regenerative substance for CKD patients.

Funding: NIDDK Support

PUB455

Subclinical Proximal Tubular Injury in Nonhospitalized Patients with Cirrhosis

Eric Luitweiler, Michael L. Granda, Bryan R. Kestenbaum. *University of Washington School of Medicine, Seattle, WA.*

Background: Cirrhosis leads to a reduction in kidney blood flow via splanchnic vasodilation and reflexive neurohormonal activation. These hemodynamic changes may adversely impact tubular health in the absence of clinically apparent kidney injury. We tested the association of cirrhosis with the urine excretion of kidney injury molecule-1 (KIM-1), a marker of tubular injury, in stable outpatients with end-stage liver disease (ESLD).

Methods: We recruited 39 adult patients with ESLD undergoing outpatient evaluation for liver transplantation. We selected a comparison group of 58 control individuals without liver disease from two previously completed studies, matched to the cirrhosis group by estimated glomerular filtration rate (eGFR). We measured urine KIM-1 concentrations in 24-hour urine samples by electrochemiluminescence (Mesa Scale Discovery). We used linear regression to quantify associations of urine KIM-1 excretion with the presence of cirrhosis and measures of liver disease severity.

Results: The cirrhosis group was characterized by a mean age of 57 ±9 years; 28% female; mean eGFR of 66 ±20 ml/min/1.73m2; and mean Model for End-stage Liver Disease (MELD) and Child-Pugh Scores of 17±4 and 8 ±2, respectively. The median urine KIM-1 excretion was 1688 pg/min (IQR 306, 2683 pg/min) in the cirrhosis group versus 180 pg/min (IQR 118, 356 pg/min) in the control group. After adjustment for eGFR, age, and sex, the presence of cirrhosis was associated with an estimated 4.0-fold greater urine excretion of KIM-1 (95% confidence interval 2.7, 6.2-fold greater; p-value <0.001). Among the cirrhosis group, higher Child-Pugh Scores, international normalized ratios (INR), and the severity of ascites were associated with higher urine excretion of KIM-1 (Figure).

Conclusions: Cirrhosis is associated with subclinical proximal tubular injury, demonstrated by increased urine excretion of KIM-1, in stable outpatients with ESLD.

PUB456

PM2.5 Induces Epithelial-to-Mesenchymal Transition by Oxidative Stress in Renal Tubular Kidney Cells

Duk-Hee Kang,[1] Dal-Ah Kim,[1] Chor ho Jo.[2] *[1]Division of Nephrology, Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Hanyang University, Seoul, Republic of Korea.*

Background: The incidence and prevalence of chronic kidney disease (CKD) are increasing worldwide. Recently, the exposure to air pollution, especially particulate matter$_{2.5}$ ($PM_{2.5}$) was newly identified to be a potential risk factor for CKD, however there are no studies on whether exposure to $PM_{2.5}$ is a direct cause of CKD occurrence and exacerbation. Epithelial-to-mesenchymal transition (EMT) of tubular cells is one of the early mechanisms of progression of renal disease. Therefore, the identification of association between fine dust and EMT may allow to reveal the casualty toward CKD.

Methods: Fine dust collected by $PM_{2.5}$ filter (Ulaanbaatar, Mongolia) was dissolved in DMSO by sonication. Renal tubular kidney cells (NRK) were treated with dissolved $PM_{2.5}$ (2 & 5 μL/mL). EMT was evaluated by morphological changes of NRK cells and the expressions of E-cadherin, α-SMA, and vimentin after the stimulation with $PM_{2.5}$ and TGF-β (5 ng/mL) by WB and immunostaining. ROS generation was assessed by DCF-DA and MitoSox staining. RNA-seq analysis (Ebiogen, Korea) was performed to investigate which upregulated/downregulated-genes are associated with $PM_{2.5}$-induced phenotype transition in NRK cells.

Results: $PM_{2.5}$ at the concentrations of 2 and 5 μL/mL did not alter LDH release and cell proliferation up to 48 hours of exposure. $PM_{2.5}$ induced EMT of NRK cells assessed by morphologic changes associated with a decreased E-cadherin expression and de-novo expression of α-SMA and vimentin. $PM_{2.5}$ also increased DCF-DA and Mito-Sox staining. RNA-seq analysis demonstrated the differences in gene expression related to EMT (16.7%), adipokine (15.9%), apoptotic process (13.7%), and oxidative stress (12.8%). Among them, lipocalin 2 (LCN2), Interleukin-11 (IL-11), and hyaluronan synthase 2 (HAS2) expression showed the highest fold difference (2.7-folds, 2.5-folds, and 2.0-folds, respectively) between control and $PM_{2.5}$-treated NRK cells.

Conclusions: This data suggest that exposure to $PM_{2.5}$ induces EMT and oxidative stress in NRK cells, which may be one of the possible mechanisms for the association between fine dust exposure and the development of renal disease.

Transcriptomic Assessment of GRP78 as a Mediator of CKD

Nikhil Uppal,[1] Pukhraj S. Gaheer,[1] Ricky Lali,[1] Richard Austin,[1,2] Matthew B. Lanktree.[1,2] *[1]Population Health Research Institute and Departments of Medicine, Health Research Methodology, and Medical Sciences McMaster University, Hamilton, ON, Canada; [2]Division of Nephrology and the Research Institute of St Joseph's Healthcare, Hamilton, ON, Canada.*

Background: Protein misfolding causes endoplasmic reticulum (ER) stress and activation of the unfolded protein response (UPR). The 78-kDa glucose-regulated protein (*GRP78*) is an ER stress-induced chaperone protein and regulator of UPR. *GRP78* overexpression protects rat ventricular cardiomyocytes from ischemia-reperfusion injury and regulates the profibrotic response to high glucose in glomerular mesangial cells. Homozygous knockout of *GRP78* is lethal in mice. We hypothesized that genetically altered *GRP78* expression or rare variants in *GRP78* would be associated with chronic kidney disease (CKD).

Methods: We assessed genetic variants' impact on *GRP78* gene expression in the expression quantitative trait loci genetics consortium (n=31,684). We used a two-sample Mendelian Randomization analysis to assess the effect of genetically predicted *GRP78* expression on CKD (n=480,698), cross-sectional eGFR (n=1,508,659), eGFR decline (n=343,339), and urinary albumin-to-creatinine ratio (uACR; n=348,964) using European ancestry summary-level genome-wide association studies (GWAS). The prevalence of *GRP78* missense and loss-of-function variants was assessed in gnomAD, BRAVO, and in 157,528 UK Biobank participants. We performed linear regression to test for association between GRP78 rare variant carrier status and kidney phenotypes adjusted for age, sex, and ancestry.

Results: The latest GWAS reports association of variants near *GRP78* and eGFR (lowest P=8.9e-09). A 13-variant Mendelian randomization instrument explained 2.8% of variability in *GRP78* expression, but was not associated with cross-sectional eGFR, eGFR decline, CKD, or uACR (P>0.05). *GRP78* is relatively intolerant of genetic variability, with a loss-of-function upper bound fraction of 0.41 and missense observed/expected ratio of 0.41. Presence of rare-variants was marginally associated with a 6.4% increase in

uACR (P=0.01), a 1.5% decline in eGFRCys (P=0.02), but not significantly associated with cross-sectional eGFR (β=-0.004,P=0.5) or CKD (OR=1.31,95% CI:1-1.73,P=0.05).

Conclusions: *GRP78* is relatively intolerant of genetic variation consistent with selection against heterozygous variation. Nevertheless, GWAS and rare variant analysis show a nominal association of variants around *GRP78* with kidney phenotypes. In contrast, genetically-predicted variation in *GRP78* expression was not associated with kidney phenotypes.

PUB458

Growth Restriction, but Not Prematurity, Is Associated with Renal Microinflammation in Early Adulthood

Liangjian Lu,[1] Chang-Yien Chan,[2,1] Chian Chau Lee,[3] Isaac Desheng Liu,[1] Hui Kim Yap.[2,1] *[1]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [2]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [3]National University of Singapore, University Health Centre, Singapore, Singapore*.

Background: Low birth weight (LBW), i.e. birth weight <2.5kg, is associated with an increased risk of adult-onset chronic kidney disease and kidney failure, but the mechanistic basis of this association is unknown. We hypothesize that reduced nephron endowment in these patients results in chronic glomerular hyperfiltration, which eventually leads to renal immune cell infiltration and inflammation, creating a pro-fibrogenic milieu. We aimed to characterize the urine immune cell and cytokine composition in young adults born LBW, and compare them with normal birth weight controls.

Methods: We recruited a cohort of 40 LBW participants, comprising 25 participants born prematurely and 15 born growth-restricted (IUGR) at term, as well as 16 age- and sex- matched normal birth weight controls. Urine immune cells were quantified by flow cytometry (markers: CD45, CD3, CD56, CD19, CD14) and urine cytokine composition by multiplex ELISA. The 3 participant groups were first compared using ANOVA, and if significant with p≤0.05, post-hoc tests were then performed with Tukey's HSD test.

Results: The 3 participant groups were comparable in terms of serum creatinine (p=0.206), Cystatin C (p=0.709), as well as urine albumin:creatinine ratio (p=0.485). Of the cell markers studied, urine CD3+ T-cell (p=0.048) and CD14+ macrophages (p=0.007) differed between groups. This was due to Term IUGR participants having a higher level of urinary CD3+ T-cells (9.5±2.2% vs 3.6±0.7%, p=0.041) and CD14+ macrophages (0.17±0.04% vs 0.05±0.01%, p=0.005) compared to controls. Participants also differed in urine IL-6 concentrations (p=0.009), with Term IUGR participants having higher urinary IL-6 compared to controls (1.1±0.3 vs 0.43±0.1 pg/mg creatinine, p=0.047).

Conclusions: Young adults who were born growth-restricted at term displayed incipient nephropathy characterized by renal microinflammation. If validated, indices of renal microinflammation can be used to identify high-risk patients for long-term follow-up, and provide a basis for early intervention using targeted immunological therapies.

Sparsentan (SPAR) vs. Irbesartan (IRB) in Patients with Focal Segmental Glomerulosclerosis (FSGS): Results from the Phase 3 DUPLEX Trial

Michelle N. Rheault,[1] Howard Trachtman,[2] Ulysses Diva,[3] Radko Komers.[3] On behalf of the DUPRO steering committee and DUPLEX investigators. *[1]Division of Pediatric Nephrology, University of Minnesota Medical School, Minneapolis, MN; [2]Division of Nephrology, Department of Pediatrics, University of Michigan, Ann Arbor, MI; [3]Travere Therapeutics, San Diego, CA.*

Background: SPAR is a dual endothelin angiotensin receptor antagonist (DEARA) that reduced proteinuria in patients with FSGS in the phase 2 DUET trial. DUPLEX evaluated the antiproteinuric and nephroprotective potential of SPAR vs active control IRB in patients with FSGS. DUPLEX met its interim efficacy endpoint (FSGS partial remission endpoint [FPRE]), with 42% of patients achieving FPRE with SPAR vs 26% with IRB at 36 wk. Here, we present results from the primary analysis.

Methods: In this phase 3 randomized trial, patients (ages 8-75 y) with FSGS, excluding secondary causes, with a urine protein/creatinine ratio (UP/C) ≥1.5 g/g and an estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m^2 at screening were randomized 1:1 to SPAR or IRB (target dose, 800 and 300 mg/d, respectively) for 108 wk. The primary endpoint was eGFR slope. Other efficacy endpoints are listed in the **Table**. Safety was assessed and evaluated by a data monitoring committee.

Results: 371 patients were randomized to SPAR (n=184) or IRB (n=187). After 108 wk, SPAR showed a 50% reduction in UP/C vs 32% with IRB, with more than twice as many patients achieving complete remission of proteinuria (**Table**). The differences in eGFR total and chronic slope for SPAR vs IRB were 0.3 and 0.9 mL/min/1.73 m^2 per year (P>.05). Additional efficacy results are listed in the **Table**. SPAR was well tolerated, with a safety profile comparable to IRB.

Conclusions: In the largest randomized trial in FSGS to date, SPAR achieved a clinically meaningful reduction in proteinuria, although the eGFR slope–based primary endpoints were not met. Overall, results support the potential clinical benefit of SPAR for FSGS. Dr Rheault and Dr Trachtman contributed equally.

Funding: Commercial Support - Travere Therapeutics

Table. Efficacy Results

Endpoint	Definition and timing	SPAR (n=184)	IRB (n=187)	Difference for SPAR vs IRB (95% CI)[a]
eGFR total slope, LS mean (95% CI), mL/min/1.73 m^2 per year[b]	From d 1 to wk 108	−5.4 (−6.9 to −3.9)	−5.7 (−7.2 to −4.3)	0.3 (−1.7 to 2.4), ns
eGFR chronic slope, LS mean (95% CI), mL/min/1.73 m^2 per year[c]	From wk 6 to 108	−4.8 (−6.3 to −3.3)	−5.7 (−7.2 to −4.2)	0.9 (−1.3 to 3.0), ns
Change in eGFR, LS mean (95% CI), mL/min/1.73 m^2	From baseline to 4 wk post treatment	−10.4 (−12.6 to −8.1)[d]	−12.1 (−14.4 to −9.9)[d]	1.8 (−1.4 to 4.9), ns
Change in UP/C, %	From baseline to wk 108	−50.0	−32.3	GMR, 0.74 (0.58 to 0.93)
FPRE, %	Defined as UP/C ≤1.5 g/g and ≥40% reduction from baseline, at wk 108	37.5	22.6	RR, 1.60 (1.13 to 2.25)
Complete remission of proteinuria, %	Defined as UP/C <0.3 g/g; at any time during the 108-wk double-blind treatment period	18.5	7.5	RR, 2.47 (1.37 to 4.45)
End-stage kidney disease, n (%)	Defined as confirmed eGFR <15 mL/min/1.73 m^2 or RRT; at any time during the study	12 (7)	21 (11)	RR, 0.58 (0.31 to 1.07)
Confirmed 50% reduction in eGFR, end-stage kidney disease, or renal death, n (%)[e]	At any time during the study	21 (11.4)	31 (16.6)	RR, 0.68 (0.43 to 1.10)

eGFR, estimated glomerular filtration rate; FSGS, focal segmental glomerulosclerosis; FPRE, FSGS partial remission endpoint; GMR, geometric mean ratio; IRB, irbesartan; LS, least squares; ns, not significant; RR, relative risk; RRT, renal replacement therapy; SPAR, sparsentan; UP/C, urine protein/creatinine ratio.
[a] Unless otherwise specified.
[b] Primary endpoint in the US.
[c] Primary endpoint in other countries.
[d] Patients who completed treatment in the double-blind period (sparsentan, n=129; irbesartan, n=136).
[e] Renal death was defined as death in a patient who reached end-stage kidney disease prior to initiating renal replacement therapy where another cause of death has not been reported.

FR-OR109

Pivotal Results of the Phase 3 PROTECT Trial of Sparsentan (SPAR) vs. Irbesartan (IRB) in Patients with Immunoglobulin A Nephropathy (IgAN)

Brad H. Rovin,[1] Jonathan Barratt,[2] Ulysses Diva,[3] Radko Komers,[3] Vlado Perkovic.[4] On behalf of the DUPRO steering committee and PROTECT investigators. *[1]Division of Nephrology, Ohio State University Wexner Medical Center, Columbus, OH; [2]Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [3]Travere Therapeutics, San Diego, CA; [4]Faculty of Medicine & Health, University of New South Wales Sydney, Sydney, NSW, Australia.*

Background: SPAR, a dual endothelin angiotensin receptor antagonist (DEARA), showed a significantly greater reduction in urine protein excretion vs IRB in patients (pts) with biopsy-proven IgAN in an interim 36-wk analysis of the PROTECT trial (−49.8% vs −15.1%, respectively; P<.0001) (Heerspink et al. *Lancet*. 2023). Based on these data, SPAR was granted accelerated approval in the US for adults with primary IgAN at risk of rapid disease progression. We will present the pivotal double-blind PROTECT trial results on the efficacy and safety of SPAR vs IRB. These results will be available after database lock in Sep 2023.

Methods: PROTECT is a phase 3, international, randomized, double-blind, parallel-group, active-controlled trial evaluating the efficacy and safety of SPAR vs IRB in adults with IgAN at high risk of progression to kidney failure despite maximized treatment with an angiotensin-converting enzyme inhibitor and/or angiotensin receptor blocker. Pts with biopsy-proven IgAN, urine protein excretion ≥1.0 g/d, and estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m^2 were randomized 1:1 to SPAR 400 mg/d or IRB 300 mg/d for up to 110 wk. The final analysis will report the 2-year rate of eGFR change (chronic and total slope), kidney composite endpoint (rate of >40% eGFR decline, kidney failure, or death), change in proteinuria by visit, rates of complete (<0.3 g/d) and partial (<1.0 g/d) proteinuria remission, and long-term safety and tolerability. Analyses used will be a mixed model random coefficients analysis (eGFR slope), mixed model for repeated measures (change in proteinuria), and logistic regression model (remission and composite endpoints).

Results: A total of 404 pts were randomized to SPAR (n=202) or IRB (n=202). We will present eGFR chronic and total slopes over 2 years, incidence of the kidney composite endpoint, percent change from baseline in urine protein-creatinine ratio through wk 110, and proportion of pts who achieved complete or partial proteinuria remission at any time within 110 wk. Safety and tolerability data will be presented.

Conclusions: The phase 3 trial results on kidney function and outcomes, proteinuria, and safety with SPAR vs IRB over 2 years may significantly impact the treatment landscape of pts with IgAN.

AYAME Study: Randomized, Double-Blind, Placebo-Controlled Phase 3 Study of Bardoxolone Methyl in Diabetic Kidney Disease (DKD) Patients

Tadao Akizawa,[1] Kengo Yamawaki,[2] Tomohiro Ichikawa,[2] Kazuya Mukai,[2] Masaomi Nangaku.[3] *[1]Showa University School of Medicine, Tokyo, Japan; [2]R&D Division, Kyowa Kirin Co., Ltd., Tokyo, Japan; [3]The University of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Bardoxolone methyl (BARD) is an activator of the Keap1-Nrf2 pathway. Previous study demonstrated that BARD improves the estimated glomerular filtration rate (eGFR). However, the phase 3 study was terminated prematurely because of an imbalance in heart failure (HF) between BARD and placebo groups. The subsequent phase 2 TSUBAKI study demonstrated no incidence of HF and an improved GFR as determined by inulin clearance in diabetic kidney disease (DKD) patients without the risk factors of HF. We conducted an event-driven study to evaluate the efficacy and safety of BARD in more than 1,000 patients.

Methods: A phase3 (AYAME) study was conducted in DKD patients and comprises a screening period, a treatment period of 3-4 years, and a post-treatment observation period of 16 weeks. Eligible patients had eGFR ≥15.0 - <60 ml/min/1.73m^2 and urinary albumin creatinine ratio (UACR) ≤3500 mg/g without the risk factors of HF. The primary and the key secondary endpoints were the time to onset of a ≥30% decrease in the eGFR or end-stage kidney disease (ESKD: dialysis, kidney transplantation or eGFR ≤6) and a ≥40% decrease in the eGFR or ESKD, respectively. Other secondary endpoints included the time to onset of ESKD. The safety endpoints were adverse events and time to onset of cardiac events, including HF.

Results: 1013 patients were råandomized (1:1) to receive BARD or placebo. The mean eGFR (standard deviation, [SD]) and UACR (SD) at baseline were 37.84 (12.64) ml/min/1.73 m^2 and 712.39 (834.22) mg/g, and were generally comparable among the groups. The primary outcome occurred in 153 of 507 patients in the BARD group and 229 of 506 patients in the placebo group (hazard ratio (HR), 0.56; 95% CI, 0.45 to 0.69; P<0.001). A key secondary outcome occurred in 122 patients in the BARD group and 172 patients in the placebo group (HR, 0.69; 95% CI, 0.55 to 0.87; P=0.0018). ESKD occurred 69 patients in the BARD group and 62 patients in the placebo group without significant differences (HR, 1.21; 95% CI, 0.86 to 1.71; P=0.2706). Cardiac events occurred 24 events in the BARD group and 26 events in the placebo group, and there were no other safety concerns.

Conclusions: AYAME study achieved its primary and key secondary endpoint without major safety concern, while BARD did not decrease the occurrence of ESKD.

Aldosterone Synthase Inhibition with or Without Background Sodium Glucose Cotransporter 2 Inhibition in CKD: A Phase II Clinical Trial

Katherine R. Tuttle,[1,2] Sibylle J. Hauske,[3] Lisa Cronin,[3] Zhichao Sun,[3] Dick de Zeeuw,[4] Hiddo J. Heerspink,[4] Peter Rossing.[5] On behalf of the Steering Committee. *[1]University of Washington, Seattle, WA; [2]Providence Inland Northwest Health, Spokane, WA; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [5]Steno Diabetes Center Copenhagen, Herlev, Denmark.*

Background: High aldosterone levels accelerate chronic kidney disease (CKD) progression. We tested the efficacy and safety of BI 690517, a novel aldosterone synthase inhibitor (ASI), in participants (pts) with CKD.

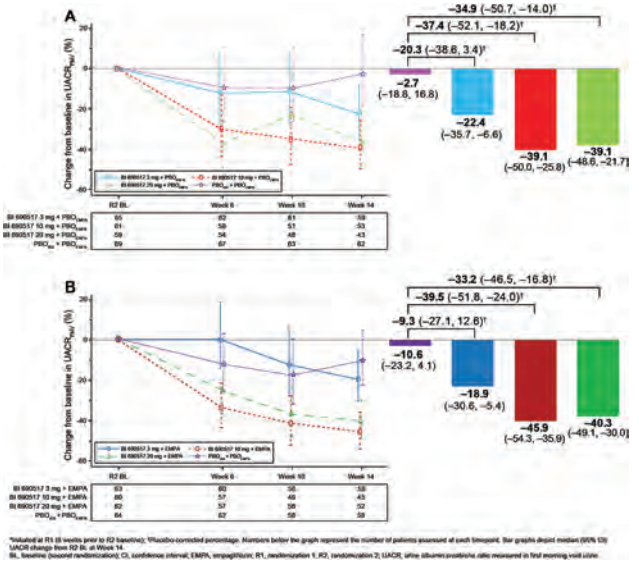
Methods: In this double-blind trial (NCT05182840), adults with CKD on a renin angiotensin system inhibitor (RASi) were first randomized (R1) 1:1 to an 8-week run-in to background (BG) empagliflozin 10 mg (EMPA) or placebo (PBO_{EMPA}) and then randomized a second time (R2) 1:1:1:1 to BI 690517 (3, 10, or 20 mg) or PBO_{ASI}.

The primary endpoint was change from R2 baseline (BL) in urine albumin:creatinine ratio (UACR) from the first morning void at Week 14. A secondary endpoint was UACR ≥30% reduction from R2 BL at Week 14.

Results: Of 714 pts randomized in R1, 586 were randomized in R2. At R2 BL, mean (SD) age was 63.8 (11.3) years, 58.4% of pts were White, 66.6% were male, and 70.6% had type 2 diabetes. BL median (IQR) UACR was 426.3 (205–889) mg/g and mean (SD) eGFR was 51.9 (17.7) mL/min/1.73m^2. BI 690517 dose dependently reduced UACR (Figure). Largest median (95% CI) PBO_{ASI}-corrected change was −39.5% (−51.8, −24.0) for BI 690517 10 mg on EMPA BG. Among BI 690517 3–20mg pts, changes in UACR ≥30% were achieved by 53.5% on EMPA BG and 43.2% on PBO_{EMPA} BG. BI 690517 (3–20mg)-related adverse events were reported in 19.2% of pts on EMPA BG and 18.5% of those on PBO_{EMPA} BG.

Conclusions: BI 690517 was well tolerated and dose dependently reduced UACR on top of BG RASi and EMPA/PBO_{EMPA} in pts with CKD. BI 690517 and EMPA showed additive anti-albuminuric efficacy that may translate into greater kidney protection.

Funding: Commercial Support - Boehringer Ingelheim



Percentage change from R2 BL in UACR up to Week 14 following BI 690517 treatment administered with A) EMPA-matched placebo or B) EMPA 10 mg.

ZENITH-CKD: A Phase 2B Study of Zibotentan in Combination with Dapagliflozin and Dapagliflozin Alone in Patients with CKD

Hiddo J. Heerspink,[1] Arihiro Kiyosue,[2] David C. Wheeler,[3] Min Lin,[4] Emma Wijkmark,[4] Glenn F. Carlson,[5] Anne-Kristina Mercier,[6] Magnus Åstrand,[5] Sebastian Ueckert,[6] Peter J. Greasley,[5] Philip D. Ambery.[7] *[1]Department of Clinical Pharmacy & Pharmacology, Universiteit Groningen Faculteit Medische Wetenschappen, Groningen, Netherlands; [2]EKI Center Building Clinic, Tokyo, Japan; [3]Department of Nephrology, University College London, London, United Kingdom; [4]Biometrics Late Development, Cardiovascular, Renal & Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]Research & Early Development, Cardiovascular, Renal & Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [6]Clinical Pharmacology and Quantitative Pharmacology, Clinical Pharmacology and Safety Sciences, R&D, AstraZeneca, Gothenburg, Sweden; [7]Clinical Late Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: Despite treatment of CKD with RAS and SGLT2is, many patients have residual albuminuria which may be associated with rapid CKD progression. The albuminuria-lowering efficacy and safety of zibotentan, a selective ET-A receptor antagonist, were examined when administered concomitantly with an SGLT2i in a phase 2b dose-ranging trial.

Methods: ZENITH-CKD, a randomized, double-blind, active-controlled trial, was conducted in 170 clinical sites in 18 countries. Adults with a urinary albumin-creatinine ratio (UACR) of 150 to 5000 mg/g and eGFR ≥20 mL/min/1.73m^2 not on SGLT2i were randomized to 1 of 6 treatment arms. Enrollment to 5 mg zibotentan monotherapy, 5 mg zibotentan/10 mg dapagliflozin, and placebo was discontinued at 62 participants. Enrollment continued across 3 other treatment arms: 0.25 mg/10 mg zibotentan/dapagliflozin, 1.5 mg/10 mg zibotentan/dapagliflozin, dapagliflozin/placebo 10 mg. The primary efficacy endpoint was change from baseline to week 12 in log-transformed UACR, assessed using mixed model repeated measures (in patients who received at least 1 dose of study treatment). Adverse events were recorded as safety endpoints. (NCT04724837)

Results: From April 28, 2021, to January 17, 2023, 447 patients were enrolled and received 0.25 mg/10 mg zibotentan/dapagliflozin (n=91), 1.5 mg/10 mg zibotentan/dapagliflozin (n=179), or 10 mg dapagliflozin/placebo (n=177). Overall, 58.4% of patients had type 2 diabetes, mean baseline eGFR was 46.7 mL/min/1.73m^2, and geometric mean UACR was 538.3 mg/g. At week 12, vs dapagliflozin alone, adjusted percentage mean change in UACR was greater in the 0.25 mg/10 mg and 1.5 mg/10 mg zibotentan/dapagliflozin groups (-27.0% [90% CI -38.4%, -13.6%] and -33.7% [90% CI -42.5%, -23.5%]). No increase in BNP, body weight, or total body water was seen for the 0.25 mg/10 mg zibotentan/dapagliflozin group; modest increases were observed in the 1.5 mg/10 mg zibotentan/dapagliflozin group. One SAE of heart failure occurred in the 0.25 mg/10 mg zibotentan/dapagliflozin group and two occurred in the 1.5 mg/10 mg zibotentan/dapagliflozin group.

Conclusions: ZENITH-CKD confirmed 0.25 mg/10 mg zibotentan/dapagliflozin is highly effective in reducing albuminuria, is well tolerated, and could be an attractive option to further delay CKD progression.

ALdosterone Antagonist Chronic HEModialysis Interventional Survival Trial (ALCHEMIST): Primary Results

Patrick Rossignol,[1,8] Faiez Zannad,[1] Ziad Massy,[2] Michel Azizi,[3] Julien Coadic,[4] Angélique Tenailleau,[4] Dominique Mottier,[5] Francis Guillemin,[1] Fatima Chorfa,[6] Delphine Maucort-Boulch,[6] Luc Frimat.[7,1] *[1]CIC-1433, Université Lorraine, CHRU Nancy Inserm, Nancy, France; [2]Nephrology Departement, Ambroise Paré, Assistance Publique - Hopitaux de Paris, Boulogne Billancourt, France; [3]Hypertension Unit and CIC, Hospital Georges Pompidou, Assistance Publique - Hopitaux de Paris, Paris, France; [4]DRCI, CHU de Brest, Brest, France; [5]CIC, CHU de Brest, Brest, France; [6]Université Lyon 1, Villeurbanne, France; Hospices Civils de Lyon, Pôle Santé Publique, Service de Biostatistique et Bioinformatique, Lyon, France; CNRS, UMR 5558, Laboratoire de Biométrie et Biologie Évolutive, Équipe Biostatistique-Santé, Villeurbanne, France; [7]Nephrology Department, Université de Lorraine, CHRU Nancy, Nancy, France; [8]Medical Specialties and Nephrology-Hemodialysis Department, Centre Hospitalier Princesse Grace, Monaco, Monaco.*

Background: There is currently no strong evidence-based pharmacological therapy to improve the excessively poor cardiovascular (CV) prognosis in chronic hemodialysis patients (HD). We aimed to investigate the effects of the steroidal mineralocorticoid receptor antagonist, spironolactone on CV outcomes in a high-risk HD population.

Methods: We conducted an international, multicenter, double-blind, randomized, placebo-controlled event-driven trial in HD patients with at least one CV comorbidity, abnormality or risk factor. Spironolactone 25 mg every other day was first administered open-label during a 4-week run-in period. Patients were excluded prior to randomization if serum potassium was greater than or equal to 5.5 mmol/l on two occasions during this run-in period or on the day of randomization. Randomized patients received spironolactone or placebo, both titrated up to 25 mg/day according to a pre-specified algorithm based on serum potassium monitoring. The primary outcome was the time to first MACE-expanded adjudicated event (cardiovascular death or non-fatal myocardial infarction (MI), acute coronary syndrome (ACS), stroke or hospitalization for heart failure (HHF)). The win ratio including 1. all-cause death 2. Time to a CV event (HHF, non-fatal MI, ACS or stroke) was tested in a hierarchical statistical strategy as secondary endpoint. We assumed that a total of 750 randomized patients followed for 2 years would provide 80% power to detect a risk reduction of the primary endpoint by 30% with a alpha risk of 5%. Assuming a 10% run-in withdrawal rate, 825 patients would have to be included in the run-in phase. Safety endpoints included incidence of severe hyperkalemia >6 mmol/L, as monitored at pre-specified visits, and as reported by investigators as serious adverse event. Clinicaltrials.gov NCT01848639

Results: First visit in first patient occurred on June 2013 and last visit in last patient occurred on November 2022. 823 patients were recruited. ALCHEMIST primary results will be presented at the ASN 2023 annual meeting.

Conclusions: ALCHEMIST was the first international double-blind randomized CV outcome trial of spironolactone vs placebo in high-risk HD.

Funding: Government Support - Non-U.S.

Effect of a Multi-Component Intervention to Improve Patient Access to Kidney Transplantation and Living Kidney Donation

Amit X. Garg,[1,2] Seychelle Yohanna,[3] Kyla L. Naylor,[4,2] Susan Q. Mckenzie,[5] Istvan Mucsi,[6,7] Stephanie N. Dixon,[4,2] Bin Luo,[4,2] Jessica M. Sontrop,[4,1] Peter G. Blake.[1,8] Enhance Access to Kidney Transplant and Living Kidney Donation (EnAKT LKD) Investigators. *[1]Medicine, Western University, London, ON, Canada; [2]ICES, Toronto, ON, Canada; [3]McMaster University, Hamilton, ON, Canada; [4]Lawson Health Research Institute, London, ON, Canada; [5]Kidney Patient and Donor Alliance Canada, Stratford, ON, Canada; [6]University of Toronto, Toronto, ON, Canada; [7]University Health Network, Toronto, ON, Canada; [8]Ontario Health, Toronto, ON, Canada.*

Background: Patients with advanced chronic kidney disease (CKD) have the best chance for a longer and healthier life if they receive a kidney transplant. However, many barriers prevent patients from receiving a transplant.

Methods: We conducted a pragmatic, two-arm, parallel-group, cluster-randomized trial of a multi-component intervention designed to target several barriers which prevent kidney transplantation and living donation. The trial included all 26 CKD programs in Ontario, Canada, from Nov 2017 to Dec 2021. These programs care for patients with advanced CKD (patients approaching the need for dialysis or receiving maintenance dialysis). Using covariate-constrained randomization, we allocated the CKD programs (1:1) to provide the intervention or usual care for 4.2 years. The intervention had 4 main components: (1) administrative support to establish local quality improvement teams; (2) transplant educational resources; (3) an initiative for transplant recipients and living donors to share stories and experiences; and (4) program-level performance reports and oversight by administrative leaders. The primary outcome was a composite of all completed steps toward receiving a kidney transplant. Each patient could complete up to 4 steps: step 1, referred to a transplant center for evaluation; step 2, had a potential living donor contact a transplant center for evaluation; step 3, added to the deceased donor waitlist; and step 4, received a transplant from a living or deceased donor.

Results: The 26 CKD programs (13 intervention, 13 usual care) during the trial period cared for 20 375 potentially transplant-eligible patients with advanced CKD (intervention [n=9780 patients], usual care [n=10 595 patients]). Despite evidence of intervention uptake, the step completion rate did not significantly differ between the intervention versus usual-care groups: 5334 vs. 5638 steps; 24.8 vs. 24.1 steps per 100 patient-years; adjusted hazard ratio 1.00 (95% CI, 0.87–1.15). Results were consistent in multiple analyses.

Conclusions: This province-wide strategy did not increase the rate of completed steps toward receiving a kidney transplant. Improving access to transplantation remains a global priority. Future efforts can build on lessons learned. Protocol: PMID 33948191 Protocol, Process evaluation: PMID 35340770 Statistical analytic plan: PMID 36438439 ClinicalTrials.gov record: NCT03329521

MDR-101-MLK Update: Operational Immune Tolerance Achieved in Living Related HLA-Matched Kidney Transplant Recipients

Dixon Kaufman,[1] Mark D. Stegall,[2] Sanjeev Akkina,[3] James B. Piper,[4] William S. Asch,[5] Stephan Busque,[6] Ahmed O. Gaber,[7] Martin L. Mai,[8] Michael E. de Vera,[9] Suzon Collette,[10] Anup M. Patel,[11] Ashesh P. Shah,[12] Erik Stites,[13] Lenuta Micsa,[14] Daniel C. Brennan.[14] *[1]University of Wisconsin System, Madison, WI; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Loyola University Medical Center, Maywood, IL; [4]Inova, Falls Church, VA; [5]Yale School of Medicine, New Haven, CT; [6]Stanford University School of Medicine, Stanford, CA; [7]Houston Methodist Hospital, Houston, TX; [8]Mayo Clinic Florida, Jacksonville, FL; [9]Loma Linda University Medical Center, Loma Linda, CA; [10]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [11]Cooperman Barnabas Medical Center, Livingston, NJ; [12]Thomas Jefferson University, Philadelphia, PA; [13]University of Colorado, Denver, CO; [14]Medeor Therapeutics, South San Francisco, CA.*

Background: We describe the updated results from a Phase 3 RCT in recipients of HLA-matched living donor (LD) kidney transplants (KTxp) who received investigational cellular product, MDR-101, for induction of immune tolerance and elimination of immunosuppressive (IS) drugs vs standard of care (SOC) (NCT03363945).

Methods: Eligible adult, recipients (R) of a 1st kidney from an HLA-matched related LD were randomized 2:1 to Investigational Arm (IA; n=20) or Control Arm (CA; n=10). Peripheral blood CD34+ and CD3+ cells for MDR-101 were collected via apheresis from the same kidney donor. IA-Rs were transplanted day (D) 0 and received rATG (D0-4), total lymphoid irradiation (10 fractions), initiation of CNI, followed by an MDR-101 infusion (D11). Steroids were withdrawn by D10 and MMF was given D11-D39. CNI monotherapy continued till D180 and tapered to complete withdrawal 1-year post-transplant (tx) if donor hematopoietic mixed chimerism was ≥5%, and no rejection (BPAR), GvHD, or kidney loss. CA-Rs received IS per institutional SOC.

Results: 20 IA-Rs received tolerance induction conditioning including MDR-101 infusion. 1 IA-R not an HLA-matched (a protocol deviation) and <6 mos of chimerism did not qualify for IS withdrawal. 19 IA-Rs successfully discontinued IS 1-year post-tx. To date, the number of IA-Rs and time remaining off IS: for 12 mos (n=17/19), 12-24 mos (n=17/19), 24 mos (n=12/14). 4 IA-Rs remain off IS and are yet to reach 24 mos off IS. 3 IA-Rs resumed IS: recurrent IgAN (18.7 mos off IS), recurrent IgAN and rejection (4.8 mos off IS), and rejection (11.2 mos off IS). No GvHD, PTLD or other malignancies occurred. No death occurred in either group. 1 IAR developed recurrent IgAN and after study completion had graft loss (4.3 years post-tx). D365 mean eGFR was 64.37 mL/min (IA-R) and 58.78 mL/min (CA-R). D730 mean eGFR was 62.37 mL/min (IA-R) and 62.22 mL/min (CA-R).

Conclusions: MDR-101 can safely achieve donor mixed chimerism and operational immune tolerance with complete elimination of all IS with no death, graft loss, or GvHD in HLA-matched LD recipients. The protocol anticipated treatment success of at least 48% IA-R IS-Free for at least 24 mos was met.

TH-PO1113

Graft Function and Other Outcomes in Kidney Transplant Recipients Converting from Immediate-Release to Prolonged-Release Tacrolimus

Bernhard K. Krämer,[1] Nassim Kamar,[2] László Kóbori,[3] Mathilde Lemoine,[4] Balazs Nemes,[5] Su Hyung Lee,[6] Hai An P. Ha,[7] Yoshihiko Watarai,[8] Jaeseok Yang,[9] Seungyeup Han,[10] Dirk R. Kuypers,[11,12] Martin Blogg,[13] Alexander Harkavyi,[13] Carola Repetur,[13] Ludmila Scrine,[13] Mohamed Soliman.[14] *[1]University Hospital, Mannheim, Germany; [2]Toulouse University, Toulouse, France; [3]Semmelweis University, Budapest, Hungary; [4]Hopital Charles Nicolle, Rouen, France; [5]University of Debrecen, Debrecen, Hungary; [6]Ajou University School of Medicine, Suwon, Gyeonggi-do, Republic of Korea; [7]Viet Duc University Hospital, Hanoi, Viet Nam; [8]Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital, Nagoya, Japan; [9]Yonsei University College of Medicine, Seoul, Republic of Korea; [10]Keimyung University School of Medicine, Daegu, Republic of Korea; [11]University Hospitals Leuven, Leuven, Belgium; [12]University of Leuven, Leuven, Belgium; [13]Astellas Pharma Europe, Ltd., Addlestone, United Kingdom; [14]Astellas Pharma Singapore Pte Ltd., Singapore, Singapore.*

Background: CHORUS (NCT02555787) was a long-term, prospective, global, non-interventional study investigating clinical outcomes in kidney transplant recipients (KTRs) converted from twice-daily, immediate-release tacrolimus to once-daily, prolonged-release tacrolimus (PRT; Advagraf®, Astellas Pharma Europe, Ltd.) under standard practice conditions.

Methods: This study enrolled KTRs (≥18 years, N=4389) who converted to PRT based on the judgment of their treating physician. Based on the post-transplant time of conversion, KTRs were grouped into early converters (ECs; ≤6 months) or late converters (LCs; >6 months). The primary endpoint was the change in renal function (measured by estimated glomerular filtration rate, eGFR) from conversion up to 5 years; secondary endpoints included graft survival (GS). GS was also assessed using subgroup variables: converters after <3 vs ≥3 years of transplant; no changes vs changes in immunosuppressive (IS) regimen (other than PRT); coefficient of variation (CV) for tacrolimus levels <35% vs ≥35%

Results: The full analysis set included 4028 KTRs (ECs, 1060; LCs, 2968). Mean eGFR at conversion was 56.1 mL/min/1.73m²; it remained stable post-conversion in the overall and LCs, with improvements in the ECs over 5 years. Kaplan-Meier estimate of 5-year GS was 95.0% (ECs, 88.1%; LCs, 97.3%). GS was higher in KTRs with no changes vs KTRs with changes in IS regimen. GS was similar in KTRs in <35% and ≥35% tacrolimus CV subgroups. GS was higher in converters after ≥3 years vs <3 years of transplant. GS was higher in LCs vs ECs across all subgroups (**Table**).

Conclusions: Results from this large cohort of KTRs showed overall stable renal function. Graft survival was high 5 years post-transplant, supporting the long-term use of PRT. In addition, some KTR subgroups (IS regimen changes, ECs with ≥35% CV, converters after <3 years) may benefit from closer monitoring.

Table. Kaplan-Meier estimate of the 5-year graft survival rate in different subgroups, % [95% CI]

	No changes in immunosuppressive regimens (other than once-daily, prolonged-release tacrolimus)	Changes in immunosuppressive regimen (other than once-daily, prolonged-release tacrolimus)	<35% tacrolimus coefficient of variation	≥35% tacrolimus coefficient of variation	Missing tacrolimus coefficient of variation	Converters with <3 years between transplantation and conversion	Converters with ≥3 years between transplantation and conversion
Overall (N=4028)	n=3519 95.0 [95.3; 96.7]	n=509 87.9 [84.7; 90.5]	n=3121 96.9 [96.3; 97.5]	n=802 91.6 [89.3; 93.6]	n=245 78.3 [72.3; 83.2]	n=2362 91.5 [90.2; 92.5]	n=1666 99.8 [99.4; 99.9]

Clinical Impact of the Predigraft/iBox System as a Clinical Decision Support for Kidney Transplant Patients' Management: Mid-Term Results of a Prospective Randomized Controlled Trial (RCT)

Carmen Lefaucheur,[1,2] Alexandre Loupy,[1,3] Sunil Daga,[4] Luis Guirado,[5] Caroline Dudreuilh,[6] Florian Grahammer,[7] Annemarie Weissenbacher.[8] *[1]Paris Institute for Transplantation and Organ Regeneration, Paris, France; [2]Hopital Saint-Louis, Paris, France; [3]Hôpital Necker, Paris, France; [4]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [5]Fundacio Puigvert, Barcelona, Spain; [6]Guy's & St Thomas' Hospital, London, United Kingdom; [7]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [8]Universitätsklinikum Innsbruck, Innsbruck, Austria.*

Background: Computer based decision support systems are emerging tools for decision-making optimization but their clinical benefit for patient care has not been demonstrated.

Methods: We designed a European multicenter RCT with 16 centers from Europe (France, UK, Spain, Germany, Austria, Israel). Kidney recipients were randomly (1:1) assigned from 3 mos up to 10 yrs after transplant to receive either SOC or management guided by a companion software Predigraft that provides automatic iBox patient risk assessment and prognostic trajectories. The primary endpoint was the number of allograft biopsies amenable to therapeutic changes. This study presents the interim period results at 9 mos after randomization.

Results: 507 total subjects were recruited, among which 252 Predigraft and 254 SOC. The mean time from transplant to inclusion was 4.4±5,7 yrs. Mean recipient and donor

age were 52±14 and 52±15 yrs respectively. Other baseline characteristics were similar between groups. The mean follow-up time after randomization was 9.6±3.6 months. In Predigraft, 398 iBox alerts were recorded among which 232 (58%) were deemed clinically relevant by physicians and 133 (33%) were followed by a change in clinical management and/or therapeutics. 61 total biopsies were performed overall, 32 Predigraft and 29 SOC respectively (incidence of 12.6 vs 11.4%, p=NS). Biopsies revealed rejection (TCMR or ABMR) in 28% Predigraft vs 10% SOC respectively (p=0.08), CNI toxicity (28% vs 17%, p=0.2), and others including BKVN, AKI, IFTA, recurrent GN and Borderline lesions (50% vs 27%, p=0.07). Finally, the rate of biopsies leading to therapeutic changes (primary endpoint) was 25/32 (78.1%) in Predigraft compared with 3/29 (10.3%) in SOC (p<0.0001). Treatment modifications mostly included change in IS regimen type, dose, target in 20/32 (62.5%) in Predigraft vs 3/29 (10.3%) in SOC respectively, p<0.001).

Conclusions: These results show the ability of an automatized computer-based decision support system to screen for allograft instability and help to improve the rate of clinically relevant biopsies enabling therapeutic changes including detection of allograft rejection.

Multi-Center International Study to Validate a Pre-Transplant Blood-Based Next-Generation Sequencing (NGS) Signature Predicting Risk of Acute Rejection After Kidney Transplant

Lorenzo G. Gallon,[1] Anthony Chang,[2] Michael J. Donovan.[3] *[1]Northwestern University, Evanston, IL; [2]Pathology, University of Chicago, Chicago, IL; [3]Verici Dx, Miami, FL.*

Background: Demographic and clinical features of both a kidney donor and recipient are utilized to estimate risk and likelihood of graft failure. Unfortunately, many of these features have performed poorly at predicting likelihood of early acute rejection (EAR). Clinically and analytically validated biomarkers are needed to assist in guiding medical management in the early months following transplant. We report on the development and validation of a novel, next-generation sequencing (NGS) biomarker assay which interrogates the immunologic profile of pre- transplant patients receiving a cadaveric donor kidney. By applying algorithm-enabled clinical decision trees, an RNA targeted NGS feature set predicting the likelihood of EAR was developed. The assay is performed in a CLIA environment to provide clinical grade results.

Methods: 14 participating sites in US, Italy, Spain, France and Australia contributed to the validation cohort of 122 participants. All participants had blood collected prior to surgery. Patients were followed at 1 and 3 month visits and had a protocol biopsy at 3 months as well as anytime for-cause; all biopsies were read centrally. Clinical endpoint of EAR was histopathology according to BANFF criteria which included TCMR 1A or higher, ABMR or mixed EAR.

Results: The assay performance results in risk classification of low risk or high-risk correlated to defined outcome of EAR on histopathology in the first 60 days following transplant producing an AUC of 0.719, p = 0.013. The sensitivity was 0.78, and the specificity was 0.64; the odds ratio was 6.133.

Conclusions: The correlation of a blood-based NGS signature with kidney biopsy histopathology provides a diverse and robust platform of enriched clinical evidence not traditionally reported in kidney transplant. A pre-transplant immunologic risk assessment tool has the potential to yield a novel, more precise level of evidence for clinicians and their patients at a critical time in their pre-surgical preparedness.

Exploring the Pharmacokinetics, Pharmacodynamics, and Safety of Apixaban in Hemodiafiltration: Insights from the HEMOCIONA Study

Miguel Hueso,[1,2] Aurema Otero,[4,5] Elena Rosselló-Palmer,[3] Juan Peris Vidal,[3] Sergi Codina Sanchez,[1] Yurema Martínez Vilar,[5] Raúl Rigo-Bonnin,[6] Nuria Lloberas,[2] Sebastián Videla Cés.[4,5] HEMOCIONA. *[1]Nephrology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [2]Nephrology, Institut d'Investigacio Biomedica de Bellvitge, Barcelona, Spain; [3]Thrombosis and Haemostasis Unit, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [4]Clinical Pharmacology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [5]Clinical Research Support Unit, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain; [6]Clinical Laboratory, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain.*

Background: Atrial fibrillation (AF) is common among hemodialysis (HD) patients, and increases the risk of stroke. Since vitamin K antagonists increase the risk of bleeding and vascular calcifications, direct oral anticoagulants (DOACs) has attracted considerable attention. However, there is limited experience with DOACs in HD patients and concerns have been raised about their potential accumulation. Consequently, DOACs are currently not recommended in HD patients. Our study aims to assess the safety of low-dose of apixaban, based on long-term their pharmacokinetic profile, for patients with nonvalvular AF undergoing hemodiafiltration.

Methods: We conducted a single-center phase 2 clinical trial to evaluate the pharmacokinetics (PK), pharmacodynamics (PD), and safety of apixaban at a dose of 2.5 mg twice daily (BID) over a period of 4 weeks. Plasma levels were obtained during the middle dialysis session of the week, as well as the day before and after for PK/PD assessments. Concentration of apixaban was directly measured in plasma, urine and dialysis wasted liquid using a validated liquid chromatography-mass spectrometry/mass spectrometry LC-MS/MS). Blood samples for the determination of Anti-FXa activity A (AXA) were collected at the same time points as the PK samples.

Results: A total of 11 patients (8 male, 3 female) with a mean age of 67±3 years old were enrolled. The main result was the demonstration of the absence of accumulation of apixaban since daily exposure (mean (%CV) AUC_{0-12}) appeared similar the day of dialysis of the first week (1030 (0.51) mcg*h/mL), and after 4 weeks (921 (0.42) mcg*h/mL). Hemodiafiltration had no impact on apixaban plasma concentration and patients without residual diuresis did not show higher apixaban levels. A close temporal relationship between apixaban plasma concentrations and AXA was observed across the dosing intervals. No bleeding events were observed.

Conclusions: Our results have significant clinical implications, as they provide PK/PD data that justify the use of 2.5 mg BID in patients with atrial fibrillation on hemodiafiltration. Our findings emphasize the importance of considering intersubject variability in drug response and adopting individualized treatment approaches.

TH-PO1117

SGLT2 Inhibition in Alport Syndrome: First Large-Scale Trial to Plan a Randomized Controlled Trial in Children

Oliver Gross, Jan Boeckhaus. For the GuARd Alport investigators, International Alport Alliance. *Nephrology and Rheumatology, Universitatsmedizin Gottingen, Goettingen, Germany.*

Background: Trials with >10,000 patients showed positive outcomes of SGLT2is in elderly patients with CKD. These trials included no children and no young adults with Alport syndrome (AS).

Methods: This multicenter, international study (NCT02378805) assessed 99 patients with AS from 12 countries after start of SGLT2i at early CKD-stages.

Results: Mean age of children (n=10) was 16 years (range 9 to 17), eGFR >90ml/min/1.73qm, and UAPR was >1.0g/gCrea. Only adults with in-label use of SGLT2i (n=89) were analyzed. At baseline, mean age was 37±14 years, eGFR 63±35 ml/min/1.73qm, and albuminuria (UACR) 1822±1484 mg/g creatinine. Because of country- and center-specific different routines and visit intervals, all data are compared to baseline (fig. 1). At V1 month 1 to 3, UACR decreased by 34% (p<0.001), and eGFR dropped by 6% (p=0.05). At V2 (mean 5.7 months), UACR dropped by 29% (p=0.003), as did eGFR by 6% (p<0.001). At V3 (11.7 months), UACR dropped by 24%, and eGFR did by 15% (n=26; p=0.001). BMI decreased from 27.8±6.3 to 27.2±6 kg/qm and serum albumin increased (3.8±0.7 vs 3.9±0.4 g/dL). Blood pressure decreased slightly from 127/82 to 126/80 mmHg. At V4 (21 months), UACR dropped by 27%, and eGFR did by 10% (n=12; p=0.02). Compared to baseline, eGFR slope changed from -13.6 (V1), -8.4 (V2), -7.7 (V3), to -4.1 ml/min/year at V4. At a total of 50 patient-years at risk, adverse drug reactions occurred in 7/66 patients (11%).

Conclusions: For the first time, the effect of SGLT2i in a large number of young patients with AS was investigated: patients were much younger than non-diabetic CKD patients in EMPA-Kidney (37 vs. 64 years), had a similar BMI and blood pressure, a much better eGFR (63 vs. 39 ml/min/qm), and a four times higher UACR (1822 vs. 461 mg/gCrea). Patients with AS showed an intermediate response in UACR reduction. In month 12 and 21, the positive effect on long-term eGFR slope is still inconclusive. For that reason, efficacy and safety of SGLT2i in children will be addressed in the upcoming first Pediatric RCT, DOUBLE PRO-TECT Alport (NCT05944016).

NAVKIDS[2] Trial: A Multi-Centre, Waitlisted, Mixed Methods, Randomized Controlled Trial of a Patient Navigator Intervention in Children with CKD

Germaine Wong. NAVKIDS[2] Trial Steering Committee. *Sydney School of Public Health, The University of Sydney, Sydney, NSW, Australia.*

Background: Inequitable access to care is a major impediment to optimal health in children with chronic kidney disease (CKD). Patient navigators help patients and caregivers to navigate complex health systems, with the goal of improving accessibility to healthcare and community supports. However, the efficacy of patient navigation in improving the overall health of children with CKD is unknown.

Methods: In this multi-center, waitlisted, randomized control trial, we randomly assigned children with CKD (aged 0-16 years, of low socioeconomic backgrounds) (1:1) to receive immediate patient navigation (immediate) or wait for six months before receiving the intervention (waitlist). The primary outcome, assessed by intention to treat, was self-rated health (SRH) of the child at six months post-randomization.

We analysed repeated measures of the primary outcome from baseline to six months post-randomisation using cumulative logit mixed effects models. Semi-structured interviews were analysed thematically to understand caregivers' perspectives on the intervention.

Results: Of 398 children who were screened, 162 were enrolled (mean age (standard deviation): 8.8 (4.8) years, boys (64.8%)), with 80 and 82 assigned to the immediate and waitlist groups, respectively. There were no differences in the child's SRH between the immediate and waitlist groups at baseline (p=0.92). There were also no cumulative differences in the child's SRH between the immediate and waitlist groups over the 6 months period (p=0.70). Caregivers reported five themes: easing mental strain, facilitating care coordination, strengthening capacity to provide care, reinforcing care collaborations, alleviating family tensions.

Conclusions: In children with CKD, the child's SRH did not differ significantly between the immediate and waitlist groups over time. However, caregivers may have gained skills and capacity related to care from the program.

Funding: Government Support - Non-U.S.

The TRANSNephro Study Examining a New Transition Model for Post-Kidney Transplant Adolescents: A Multicenter, Randomized Controlled Trial

Lars Pape,[1] Anika Großhennig,[2] Jenny Pruefe,[1] Martin Kreuzer.[1] Study Group of the German Society of Pediatric Nephrology. *[1]Pediatrics II, Universitatsklinikum Essen, Essen, Germany; [2]Biostatistics, Medizinische Hochschule Hannover, Hannover, Germany*.

Background: Allograft loss is highest in adolescents due to non-adherence and transfer of health care. This multicenter, randomized controlled trial aimed to evaluate whether support by a central case manager and a corresponding app during transition may improve the outcome.

Methods: Adolescent patients in 18 German and Austrian centers one year before planned transfer were randomized 1:1 to a control group that received transition as by center standard or to an intervention group. The intervention consisted of a central case manager, a communication app, and joined transition rounds for one year before and one after transfer. Primary endpoint was the coefficient of variation (CoV) of the trough level of the Calcineurininhibitor as a surrogate marker for medication adherence. Important secondary endpoints were acute rejections, graft loss, eGFR, and quality of life. For the assessment, least square (LS) mean differences and corresponding 95% confidence intervals (CIs) were estimated within an analysis of covariance (ANCOVA) model.

Results: A total of 220 patients was assessed for eligibility. Of these, 102 patients were randomized, 49 to the intervention and 53 to the control group. We analyzed 84 patients in the modified intention-to-treat (mITT) analysis (38 intervention vs 46 control patients) and 60 patients in the per protocol (PP) analysis (25 intervention vs 35 control patients). No difference in CoV was observed between the two groups, neither in the mITT (LS mean difference [95% CI]:0.01 [-0.17, 0.18], p=0.9574) nor in the PP analysis (LS mean difference [95% CI]:-0.01 [-0.19, 0.16], p=0.8748). We observed a trend for a lower mean eGFR at adult clinic outpatient phase in the intervention group. We saw only low numbers of graft-related events and observed no differences between the groups with respect to quality of life.

Conclusions: The addition of our case-manager-based intervention to standard of care transition, did not improve adherence and other outcome parameters in adolescent kidney graft recipients. We assume that non-adherent patients may have decided not to take part in the trial, as adherence was already good at study start. It thus is a future challenge to design multicenter trials on transition that include multiple interventions for a better transition in order to stop the long-term decrease in graft function.

TH-PO1120

Limited Antiproteinuric Efficacy of Dapagliflozin (DPG) in Adolescents with Proteinuric CKD

Swathi Ramakrishna, Aditi Sinha, Arvind Bagga. *Pediatrics, All India Institute of Medical Sciences, New Delhi, India*.

Background: While reducing proteinuria is renoprotective in CKD, it might persist despite renin-angiotensin-aldosterone (RAAS) blockade. SGLT2 inhibitors, known to be antiproteinuric in adult-onset CKD, have not been tested in children.

Methods: This single-center trial examined the antiproteinuric efficacy & safety of DPG in adolescents with CKD (CTRI/2022/04/042032). After written consent & baseline evaluation, consecutive eligible patients, 11-19 yr old with eGFR >45 ml/min/1.73 m^2 & proteinuria >0.5 g/m^2/d despite optimal RAAS blockade, received Dapavel® at 5 mg/d x 2-wk, followed by 10 mg/d x 10-wk. Biochemistry & 24-hr urine protein/albumin were repeated at 4, 8 & 12-wk, and ambulatory blood pressure at 12-wk.

Results: Of 49 screened, 25 patients (76% boys, chiefly glomerular CKD), were enrolled at median eGFR 93 ml/min/1.73 m^2 & proteinuria 1.4 g/m^2/d (**Table 1**). **Fig. 1** shows outcomes at 4 & 12-wk. At 12-wk, proteinuria declined by median 1.3% and eGFR by 13.4%; 4 (16%) patients achieved the FSGS proteinuria reduction endpoint. 3 patients noted giddiness; none had serious adverse events.

Conclusions: Therapy with DPG for 12-wk has limited antiproteinuric efficacy in adolescents with CKD. Controlled studies should examine the antiproteinuric effect and optimal dose & duration of SGLT2 inhibitors in children.

Identification of a Hypertensive Endotype with a Median Treatment Effect of -32mmHg in Response to the Novel Aldosterone Synthase Inhibitor Lorundrostat

Borut Cizman,[1] Luke J. Laffin,[2] Natasa Rajicic,[3] David M. Rodman.[1]
[1]Mineralys Therapeutics, Radnor, PA; [2]Cleveland Clinic Center for Clinical Research, Cleveland, OH; [3]Cytel Inc, Waltham, MA.

Background: Uncontrolled and treatment-resistant hypertension are common challenges faced by clinicians. We previously reported the novel aldosterone synthase inhibitor, lorundrostat, 25mg BID, 50mg QD or 100mg QD, demonstrated median serum aldosterone reduction of 65-70% and observed mean systolic BP(SBP) reduction of -10.1, -13.2 and -14.1mmHg, respectively (n=25-28), vs placebo (-4.1 mmHg, n=29). The top quartile of the pooled group (n=81) had a median [IQR] SBP reduction of -32mmHg (n=21, [-37.5 to -27]); the bottom quartile had no change (Fig 1).

Methods: To identify predictive factors differentiating these groups, BP response to lorundrostat 100mg QD was compared in subjects with low plasma renin activity (PRA) ≤1.0ng/ml/hr vs PRA >1.0ng/ml/hr.

Results: Low PRA was not a useful predictor of response (low [n=25] -12.1 [2.68] mmHg, normal to high [n=30] -11.4 [2.48] mmHg). A correlation was observed between BMI and SBP reduction (r= -0.27, p=0.017). In the planned development doses of 50mg and 100mg QD, reduction in placebo-adjusted median (CI) SBP of -16.7 (-25.5, -7.9) mmHg and -12.3 (-21.6, -3.1) mmHg in subjects with BMI ≥30kg/m^2 (n=15,12), respectively, was observed (p=0.002 and 0.030). No significant effect of lorundrostat on SBP in subjects with BMI 25-30kg/m^2 (n=11,9) was seen (2.2 and -4.5 mmHg, respectively). Elevated baseline BP was similarly predictive of a favorable median SBP reduction in the 50mg and 100mg QD cohorts (lowest tertile of baseline SBP -3.5, -2.5 mmHg, highest tertile -34.3, -17.5mmHg, respectively), possibly due to the relative importance of aldosterone-mediated hypertension in obese individuals. A positive association was also observed between obesity and serum leptin at baseline (r=0.47, p<0.001).

Conclusions: While this association does not establish cause and effect, serum leptin is a direct stimulus for adrenal aldosterone production, and its investigation as a predictor of lorundrostat response warrants further investigation.

Wearable Device for Noninvasive Blood Pressure Monitoring of ICU Patients

Forrest Miller. *Alio, Broomfield, CO.*

Background: Blood pressure (BP) is a cardinal vital sign used in cardiovascular clinical decision-making. The traditional approach for BP measurement in intensive care units (ICU) involves the use of an invasive arterial line (A-line). A-line measurements require technique and practice and introduce the risk of clinical complications that could result in thrombosis or sepsis. This study evaluated the performance of cuffless BP monitoring with a novel wearable device ("SmartPatch") compared to the gold standard A-line.

Methods: A retrospective IRB-approved study was conducted to evaluate the performance of an algorithm to track BP metrics-systolic blood pressure (SBP), diastolic blood pressure (DBP) and mean arterial pressure (MAP)–noninvasively and compare them against invasive arterial line (on left radial) values in 26 subjects. Simultaneous arterial line BP and photoplethysmography (PPG) data from SmartPatch were collected from post-surgery patients admitted to a neuro-ICU unit over an average of 2 hours. The PPG data was pre-processed, assessed for signal quality, and fed into an Artificial Neural Network (ANN) model to train with the A-line BP data as reference.

Results: A total of 6.07 hours of data was segmented into 6 sec PPG recordings resulting in ~1900 data points to be analyzed. An ANN model was trained and validated with leave one out-cross validation (LOO-CV) to tune the model parameters and assess the performance. Mean of errors and Pearson correlation coefficient r were used to assess the performance of the ANN model. The mean of errors and the experimental standard deviation for SBP was: -1.207 (SD: 9.17) mmHg, MAP: -0.144 (SD: 5.09) mmHg and DBP: -0.161 (SD: 5.10) mmHg. These values fall within the limits set by the ISO 81060-2 (2018) standard. The ANN-generated BP values were correlated to the A-line with Pearson r = 0.81 (SBP), 0.68 (DBP) and 0.79 (MAP).

Conclusions: The ANN model was trained using LOO-CV to predict SBP, DBP & MAP. The results demonstrated quantitative accuracy within the limits set by the ISO 81060-2 (2018) standard when validated against the A-line BP. This noninvasive cuffless BP measurement from a wearable device could enable more consistent, accurate, and cost-effective patient care in remote monitoring settings.

Long-Term Renal Benefit with Nefecon in Chinese Patients with Primary Immunoglobulin A Nephropathy: Two-Year NefIgArd Trial Results

Hong Zhang,[1] Jens Kristensen,[2] Andrew M. Stone,[3] Bei Wang,[4] Lisa H. Ying,[4] Zhengying Zhu.[4] *[1]Peking University First Hospital, Beijing, China; [2]Calliditas Therapeutics AB, Stockholm, Sweden; [3]Stone Biostatistics Ltd., Crewe, United Kingdom; [4]Everest Medicines Ltd., Shanghai, China.*

Background: Immunoglobulin A (IgA) nephropathy (IgAN) is most prevalent in people of East Asian ancestry. Nefecon is a novel targeted-release oral budesonide product designed to act in the distal ileum to reduce excess galactose-deficient IgA1 production. The 2-year NefIgArd trial demonstrated that Nefecon 16 mg/day for 9 months led to a statistically significant treatment benefit on estimated glomerular filtration rate (eGFR) with Nefecon vs placebo. Here, we present results for all patients enrolled in NefIgArd from mainland China, including previously unreported patients.

Methods: NefIgArd was a global, double-blind Phase 3 study. Patients with primary IgAN on optimized supportive care were randomized 1:1 to 9 months of Nefecon 16 mg/day or placebo, followed by a 15-month observational period off study drug.

The 9-month primary endpoint was change in urine protein-creatinine ratio (UPCR). The 2-year primary endpoint was time-weighted average of eGFR over 2 years.

Results: Baseline characteristics of all 62 Chinese patients were similar to the global study population and were balanced across treatment arms. There was a 9.58 mL/min/1.73 m^2 (95% CI 1.95, 19.78) treatment benefit in the 2-year primary endpoint with Nefecon vs placebo (3.74 vs 13.32 mL/min/1.73 m^2 average eGFR decline, respectively). At 24 months, the mean absolute changes in eGFR from baseline (Fig. 1) suggested that 66% of the eGFR decline observed with placebo could be prevented with 9 months of Nefecon treatment. Mean UPCR reduction was 31% greater at 9 months and 52% greater over 12–24 months with Nefecon vs placebo. No new safety signals were identified.

Conclusions: Compared with placebo, 9 months of Nefecon treatment provided clinically relevant preservation of eGFR and durable proteinuria reduction over 2 years, supporting a disease-modifying effect in Chinese patients with primary IgAN.

Sibeprenlimab in Patients with IgA Nephropathy: A Phase 2 Trial

Jonathan Barratt,[1] Mohit Mathur,[2] Bobby Chacko,[3] Tak Mao D. Chan,[4] Laura Kooienga,[5] Kook-Hwan Oh,[6] Manisha Sahay,[7] Yusuke Suzuki,[8] Muh Geot Wong,[9] Jill Yarbrough,[2] Jing Xia,[10] Brian J. Pereira.[2] *[1]John Walls Renal Unit, Leicester General Hospital, Leicester, United Kingdom; [2]Visterra, Inc., Waltham, MA; [3]Nephrology and Transplantation, John Hunter Hospital and University of Newcastle, Newcastle, NSW, Australia; [4]University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [5]Colorado Kidney Care, Denver, CO; [6]Seoul National University College of Medicine, Seoul, Republic of Korea; [7]Osmania General Hospital, Hyderabad, India; [8]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [9]University of Sydney, Sydney, NSW, Australia; [10]Otsuka Pharmaceutical Development & Commercialization Inc., Princeton, NJ.*

Background: A Proliferation-Inducing Ligand (APRIL) is implicated in the pathogenesis of immunoglobulin A nephropathy (IgAN). Sibeprenlimab is a humanized IgG2 monoclonal antibody that blocks APRIL signaling.

Methods: VIS649-201 (NCT04287985) is a global, multicenter, randomized, double-blind, placebo-controlled study evaluating monthly intravenous (IV) sibeprenlimab 2, 4 or 8 mg/kg added to background optimized renin–angiotensin–aldosterone system blockade for 12 months in adults with IgAN. Patients with estimated glomerular filtration rate (eGFR) ≥30 mL/min/1.73 m^2, and proteinuria ≥1.0 g/d or urine protein creatinine ratio (uPCR) ≥0.75 g/g, were included.

Results: 155 participants were randomized: 56.8% male; 74.2% Asian; median age 39 years. At Month 12, compared with placebo, sibeprenlimab groups demonstrated significant reductions in 24-hour uPCR (Figure, Table) and clinically relevant smaller changes in eGFR (sibeprenlimab, −2.7 to +0.2 mL/min/1.73 m^2; placebo, −7.4 mL/min/1.73 m^2; Table). The incidence of treatment-emergent adverse events (TEAEs) was 78.6% (sibeprenlimab pooled) and 71.1% (placebo), with comparable distribution of serious, severe, and drug-related TEAEs.

Conclusions: These results suggest that IV sibeprenlimab may provide an effective and well-tolerated treatment option to slow disease progression of IgAN, and support the ongoing Phase 3 VISIONARY trial of subcutaneous sibeprenlimab in patients with IgAN (NCT05248646).

Funding: Commercial Support - Visterra, Inc. (Waltham, MA), a member of the Otsuka family of companies.

Povetacicept, an Enhanced Dual BAFF/APRIL Antagonist, in Autoantibody-Associated Glomerulonephritis (GN)

James A. Tumlin,[1,2] Harmeet Singh,[3] Frank B. Cortazar,[4] Arvind Madan,[5] Jonathan Barratt,[6] Brad H. Rovin,[7] Hong Zhang,[8] Rupert H. Davies,[9] Amanda M. Enstrom,[9] Allison G. Chunyk,[9] Heather Thomas,[9] Jiahua Li,[9] Sreedhar A. Mandayam.[10] *[1]NephroNet Clinical Trials Consortium, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Western Nephrology, Arvada, CO; [4]New York Nephrology Vasculitis and Glomerular Center, Watervliet, NY; [5]Central Florida Kidney Specialists, Orlando, FL; [6]University of Leicester, Leicester, United Kingdom; [7]The Ohio State University Wexner Medical Center, Columbus, OH; [8]Peking University First Hospital, Beijing, China; [9]Alpine Immune Sciences, Inc., Seattle, WA; [10]UT MD Anderson Cancer Center, Bellaire, TX.*

Background: Inhibition of BAFF and/or APRIL has shown promise in IgA nephropathy (IgAN), primary membranous nephropathy (pMN), and lupus nephritis (LN), with the potential to exert a disease-modifying effect. Povetacicept (ALPN-303) is an Fc fusion of a variant TACI domain engineered for more potent dual BAFF/APRIL inhibition vs WT TACI or anti-BAFF or -APRIL Abs. In healthy volunteers, povetacicept was well tolerated and reduced Ig (including Gd-IgA1) levels and Ab-secreting cells. This is a report of an open-label, multiple ascending dose experience with povetacicept in GN.

Methods: RUBY-3 (NCT05732402) is a ph 1b/2a study of povetacicept 80 or 240 mg SC Q4W for 24 wk, with an optional 24-wk extension. Eligible participants (pts) are aged ≥18 y with biopsy-confirmed IgAN, pMN, or LN, and on maximally tolerated ACEi/ARB therapy, with well-controlled BP, and disease-specific immunosuppressive therapy where applicable. Primary objective is safety; secondary objectives include PK, PD, immunogenicity, biomarkers, and efficacy.

Results: As of 1Sep23, 12 pts with IgAN and 1 with pMN have enrolled at the lower povetacicept dose level of 80 mg; 6 and 1 pts, respectively, have completed ≥12 wk. The 240-mg IgAN cohort has also begun enrolling. Povetacicept has been well tolerated, with no serious or severe TEAEs, IgG <3 g/L, or administration-related reactions. In IgAN, UPCR was reduced by 30% at 12 wk (n=6) and expected decreases in Ig levels were seen (**Fig**). The first enrolled pt achieved a urinary protein excretion level below the threshold of detection (<0.56 g/g) by 24 wk, preceded by a 43% reduction in Gd-IgA1 at 4 wk. In pMN (n=1), a 39% UPCR reduction (**Fig**) and 77% reduction in anti-PLA2R were seen at 12 wk. Updated data will be presented.

Conclusions: Initial experience indicates povetacicept is well tolerated during multiple-dose administration in GN, with highly encouraging early reductions in UPCR and disease-specific biomarkers in pts with IgAN and pMN.

Clinical Value of Adding Dapagliflozin in Patients with Nephrotic Syndrome

Magdy ElSharkawy, Nahla M. Teama, Mohamed M. Ahmed, Ahmed Emara.
Internal Medicine & Nephrology, Ain Shams University Faculty of Medicine, Cairo, Egypt.

Background: The potential utilization of SGLT2 inhibitors in glomerular disease patients undergoing immunosuppression therapy has remained underexplored. This study evaluates the clinical impact of dapagliflozin in non-diabetic primary nephrotic syndrome patients.

Methods: We conducted a randomized controlled clinical trial with 60 non-diabetic primary nephrotic syndrome patients, equally assigned to dapagliflozin and control groups. The dapagliflozin group received dapagliflozin 10 mg/day in addition to standard care, while the control group received standard care alone. Baseline characteristics, including age, gender, nephrotic syndrome etiology, proteinuria levels, estimated glomerular filtration rate (eGFR), and immunosuppression doses, were well-matched. Both groups were followed for 6 months. 1ry outcomes included changes in proteinuria (measured by urine PCR, UPCR) and eGFR. 2ry outcomes encompassed alterations in body weight and lipid profile changes. Pregnant or breastfeeding females and patients with secondary nephrotic syndrome were excluded.

Results: Both groups exhibited significant reductions in proteinuria after 6 months, with the dapagliflozin group achieving a mean UPCR reduction of -94.7%, and the control group -86.7% ($p < 0.001$). However, the comparative percentage change in proteinuria between both groups did not reach statistical significance ($p = 0.158$). Dapagliflozin initially led to a transient eGFR decline followed by recovery, while the control group maintained stable eGFR. Dapagliflozin also resulted in a significant mean body weight reduction of 3.91 kg ($p < 0.001$) and notable improvements in triglyceride levels compared to the control group ($p = 0.045$). Although no major safety concerns arose, the dapagliflozin group exhibited a slightly higher incidence of urinary tract infections.

Conclusions: In primary nephrotic syndrome patients, adjunct dapagliflozin may enhance the standard of care. While notable, the reduction in proteinuria was comparable to that of the control group by the study's end. Furthermore, after 6 months, eGFR remained stable in both groups. However, significant weight loss and serum triglyceride reduction were particularly pronounced in the dapagliflozin group. Further long-term investigations are necessary to address potential immunosuppression-related confounding effects in patients with primary glomerular disease.

TH-PO1127

Efficacy and Safety of Ravulizumab in a Phase 2 Randomized Controlled Trial in IgA Nephropathy

Jonathan Barratt,[1] Jose Luis Rocha Castilla,[2] Dario Roccatello,[5] Katherine Garlo,[3] Kara Rice,[3] Richard A. Lafayette.[4] *[1]Department of Cardiovascular Sciences, University of Leicester, Leicester, United Kingdom; [2]Department of Nephrology, Hospital Universitario Virgen del Rocio, Sevilla, Spain; [3]Alexion, AstraZeneca Rare Disease, Boston, MA; [4]Stanford Glomerular Disease Center, Stanford University Medical Center, Stanford, CA; [5]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: IgA nephropathy (IgAN) is the most prevalent primary glomerular disease, often progressing to ESKD. Complement activation leads to glomerular damage by immune complex deposition and release of proinflammatory cytokines. Terminal complement inhibition specifically targets the pathophysiology of IgAN and may provide improved renal outcomes.

Methods: This primary analysis of a phase 2 RCT (NCT04564339) evaluated ravulizumab (RAV) (IV; weight-based dosing Q8W) vs placebo (PBO) in adults with primary IgAN. Eligible patients (pts) (18–75 years) with biopsy-confirmed IgAN, proteinuria ≥1g/d, on stable maximally tolerated RASi with stable blood pressure ≥3 months were enrolled. The primary endpoint was % change in proteinuria from baseline to week (wk) 26 based on 24-hour urine. Secondary endpoints included spot UPCR and change in baseline eGFR at wk 26, safety, and PK/PD.

Results: 66 pts were randomized 2:1 to RAV (n=43) or PBO (n=23). Mean age was 40.1 years, 46% were female, and 21% were Asian. At 26 wks, proteinuria reduction was greater with RAV vs PBO, 40.3% vs 10.9% (treatment effect 33.1%, 90% CI, 14.7%, 47.5%; p=0.0012). In RAV-treated pts, proteinuria reduction was rapid and sustained through wk 26 (**Figure 1**) and eGFR remained stable. RAV was well-tolerated with a safety profile similar to that of PBO and no new safety concerns **(Table 1)**.

Conclusions: This analysis supports clinically meaningful efficacy of RAV based on rapid and sustained proteinuria reduction, providing proof-of-concept for a phase 3 trial of RAV as a potential treatment for IgAN.

Funding: Commercial Support - Alexion, AstraZeneca Rare Disease

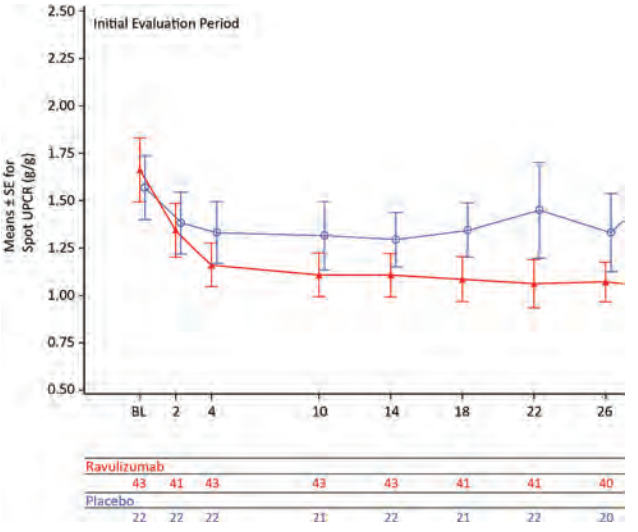

Table 1: Treatment-emergent adverse events up to 26wks

	Ravulizumab N=43	Placebo N=23
Any adverse event, n (%)	32 (74.4)	19 (82.6)
Investigator-assessed as related to study drug	9 (20.9)	6 (26.1)

Long-Term Nedosiran Safety and Efficacy in Primary Hyperoxaluria Type 1 (PH1): Interim Analysis of PHYOX3

Jaap Groothoff,[1] Anne-Laure A. Sellier-Leclerc,[2] Lisa Deesker,[1] Justine Bacchetta,[2] Gesa Schalk,[5] Burkhard Toenshoff,[4] Graham W. Lipkin,[7] Sandrine Lemoine,[8] Horacio Plotkin,[3] Thomas Bowman,[3] Jing Zhou,[3] Bernd Hoppe.[6,3] *[1]Department of Pediatric Nephrology, Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [2]Pediatric Nephrology Rheumatology Dermatology Unit, Hospices Civils de Lyon, Lyon, France; [3]Dicerna Pharmaceuticals, Inc., a Novo Nordisk Company, Lexington, MA; [4]Department of Pediatrics I, University Children's Hospital, Heidelberg, Germany; [5]Pediatric Nephrology Center Bonn, Bonn, Germany; [6]German Hyperoxaluria Center, Pediatric Nephrology Center Bonn, Bonn, Germany; [7]Department of Nephrology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [8]Hospices Civils de Lyon, Lyon, France.*

Background: Primary hyperoxaluria (PH) is a family of rare genetic disorders of hepatic glyoxylate metabolism leading to oxalate overproduction, causing calcium oxalate stones, and may result in kidney damage/failure. Nedosiran is an RNAi therapy in development for treatment of PH. Nedosiran silences hepatic LDH expression encoded by the *LDHA* gene to reduce oxalate production.

Methods: This 30-month interim analysis of the ongoing PHYOX3 study (NCT04042402) reports long-term safety/efficacy of monthly s.c. nedosiran in participants with PH1 who continued from a single-dose nedosiran trial PHYOX1 (NCT03392896). Participants (≥6 yrs) who had no prior kidney/liver transplant, dialysis, or evidence of systemic oxalosis were eligible.

Results: Thirteen participants with PH1 rolled into PHYOX3. At baseline, mean (SD) age was 24 (6.6) years (53.8% female; 61.5% White) and mean (SD) estimated glomerular filtration rate (eGFR) was 77.6 (21.82) mL/min/1.73m^2. Mean eGFR remained stable (62–84.2 mL/min/1.73m^2) to month 30. Mean urinary oxalate (Uox) excretion showed a sustained reduction from baseline (≥60%) to month 30 (**Figure**). At every visit, at least 10 (76.9%) participants achieved normal (<0.46 mmol/24h; upper limit of assay-normal [ULN]) or near-normal (≥0.46 to <0.60 mmol/24h; ≥ULN to <1.3 × ULN) 24h Uox excretion. All participants experienced ≥1 adverse event (AE), mostly mild or moderate severity (76.9% treatment-related). Three serious AEs were reported (not treatment-related). Of 398 total injections in the study, 2.5% had an injection-site reaction. There were no deaths or study discontinuations due to AEs.

Conclusions: Nedosiran was well-tolerated in patients with PH1 and resulted in a sustained reduction in Uox excretion for up to 30 months. No safety signals were identified to date. Analysis of long-term effects on kidney function are ongoing.

Funding: Commercial Support - Dicerna Pharmaceuticals, Inc., a Novo Nordisk Company (Lexington, MA)

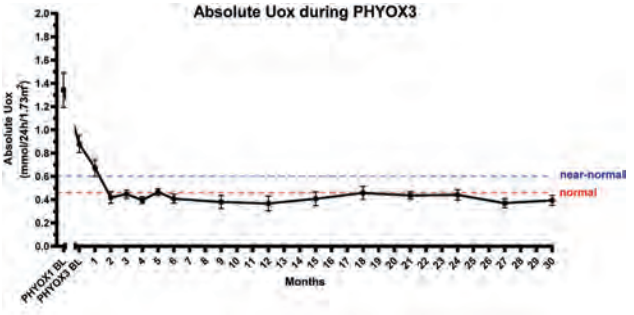

Figure. Sustained Uox reduction from baseline with once-monthly nedosiran. Mean (±SEM) absolute Uox from baseline (BL); n=13 for all visits except month 4 (n=12). Dashed lines represent normal/near-normal 24h Uox excretion.

The Kidney Transplant Fast Track (KTFT) Intervention Reduced Time to Kidney Transplant Waitlisting

Larissa Myaskovsky,[1] Arjun L. Kalaria,[2] Chethan M. Puttarajappa,[2] Yue-Harn Ng,[3] Yuridia Leyva,[1] Yiliang Zhu,[4] Miriam E. Velez-Bermudez,[1] Cindy L. Bryce,[6] Chung-Chou H. Chang,[2] L. Ebony Boulware,[5] Amit D. Tevar,[2] Mary Amanda Dew.[2] *[1]Center for Healthcare Equity in Kidney Disease, University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Washington School of Medicine, Seattle, WA; [4]University of New Mexico School of Medicine, Albuquerque, NM; [5]Wake Forest University School of Medicine, Winston-Salem, NC; [6]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Background: Kidney transplantation (KT) is the optimal treatment for end-stage kidney disease (ESKD), but the KT evaluation process is lengthy, time consuming, and burdensome to patients. In December 2012, our transplant center implemented a one-day streamlined and coordinated-care evaluation process, Kidney Transplant Fast Track (KTFT), but it has not been evaluated for efficacy (i.e., reduced time to waitlisting and KT receipt).

Methods: In 2015, we initiated a quasi-experiment to determine the efficacy of the KTFT (n=1118) compared to usual care historical controls (n=1152) from our previous cohort study. We conducted a pre-transplant workup interview with all participants and followed their transplant status via medical record review through 08/2022. Also, we examined whether cultural factors (e.g., medical mistrust, health literacy, religious objection) predicted time to waitlisting and KT. We used Fine-Gray proportional hazards modeling to examine predictors of time from evaluation to waitlisting and KT receipt, controlling for demographic and medical factors.

Results: Over a 7-year follow-up period, compared to historical controls, KTFT patients had a 44% greater chance of being wait-listed (SHR=1.44, CI=1.26-1.63, p<.0001). There was a non-statistically significant trend toward higher KT rates. Greater medical mistrust or religious objections to transplantation uniquely predicted time to waitlisting. Medical mistrust, religious objection, and lower health literacy also uniquely predicted longer time to KT.

Conclusions: We developed an effective streamlined coordinated care evaluation process for ESKD patients that reduced the time to complete evaluation and increased the rates of transplant waitlisting. We also identified unique cultural predictors of barriers to waitlisting and KT.

Twice Weekly vs. Thrice Weekly Hemodialysis in Patients with Residual Kidney Function

Seolhyun Lee,[1] Nhat M. Pham,[3] Christian G. Bolanos,[1] Saniya S. Bonde,[1] Timothy W. Meyer,[1,2] Tammy L. Sirich.[1,2] *[1]Medicine, Stanford University, Palo Alto, CA; [2]Medicine, Veterans Affairs Palo Alto, Palo Alto, CA; [3]Medicine, Santa Clara Valley Medical Center, San Jose, CA.*

Background: The most recent 2015 update of the Kidney Disease Outcomes Quality Initiative (KDOQI) dialysis adequacy guidelines increased the contribution assigned to residual kidney function in calculating standard Kt/V_{urea} (stdKt/V). However, no study has yet assessed the effect of prescribing twice weekly hemodialysis (HD) according to this guideline on patients' symptoms or uremic solute levels.

Methods: 24 HD patients with residual kidney urea clearance (Kru) 4.7±1.8 ml/min completed a cross-over trial comparing 4 weeks of twice weekly (2X) HD and 4 weeks of thrice weekly (3X) HD (NCT03874117). Patients were enrolled if they had Kru >2.5 ml/min and had been on HD for at least 2 months. During the 2X period, HD was prescribed to achieve stdKt/V 2.2 incorporating Kru using the 2015 KDOQI guidelines. During the 3X period, HD was prescribed to achieve a per treatment spKt/V 1.3 regardless of Kru. Symptom scores and pre-treatment plasma levels of urea, secreted solutes p-cresol sulfate (PCS) and hippurate (HIPP), and beta-2 microglobulin (β2m) were compared at the end of each 4-week period.

Results: Symptoms were significantly better with 2X HD, as assessed by the KDQOL36 Symptom component (2X: 86±14 vs. 3X: 82±18, p 0.001), Dialysis Symptom Index (2X: 26±26 vs. 3X: 33±31, p 0.008), and post-dialysis recovery time (2X: 1.6±0.8 vs. 3X: 1.9±1.0, p 0.01). 2X HD provided adequate stdKt/V of 2.7±0.5 without a significant increase in treatment time (2X: 195±21 min vs. 3X: 191±17 min, p 0.07). Kru, ultrafiltration rate, and pre-treatment plasma potassium were similar, and no patients were withdrawn for fluid overload or hyperkalemia. Plasma analysis showed an expected higher pre-treatment level of urea with 2X HD (76±22 vs. 54±13 mg/dl, p <0.001) while the levels of PCS (4.0±1.6 vs. 3.7±1.3 mg/dl, p 0.39), HIPP (2.7±3.0 vs. 2.2±1.9 mg/dl, p 0.84), and β2m (22±7 vs. 21±6 mg/L, p 0.80) were not significantly higher with 2X than 3X HD.

Conclusions: We show that 2X HD can be safely prescribed with the increased contribution assigned to Kru by the 2015 KDOQI guidelines. With 2X HD, symptoms were improved and the continuous function of the residual kidneys controlled fluid gain, potassium, and plasma levels of uremic solutes without a need to increase treatment time.

Hemodialysis Vascular Access Complications: Insights from the ASCEND-D Trial

Renato D. Lopes,[1] Aleix Cases,[2] Brian Claggett,[3] Laura M. Dember,[4] Nisha Bhatt,[5] Angela R. Jones-Leone,[5] Amy M. Meadowcroft,[5] Mary O. Muoneke,[5] Prerna Ranganathan,[5] Lin Taft,[5] Ajay K. Singh.[3,6] *[1]Duke University Medical Center, Durham, NC; [2]Hospital Clinic of Barcelona, Barcelona, Spain; [3]Brigham and Women's Hospital, Boston, MA; [4]University of Pennsylvania, Philadelphia, PA; [5]GSK, Collegeville, PA; [6]Harvard Medical School, Boston, MA.*

Background: Daprodustat (Dapro) is a hypoxia-inducible factor–prolyl hydroxylase inhibitor (HIF-PHI) approved in the United States for treating anemia of chronic kidney disease (CKD) in adult patients (pts) receiving dialysis for at least 4 months. Dapro provides an oral alternative to erythropoiesis-stimulating agent (ESA) therapy. There are concerns that increasing hemoglobin in the dialysis population, such as with ESAs and HIF-PHIs, may cause thromboembolic events (TEEs). In the phase 3 ASCEND-D study, which randomized (1:1) 2964 pts with CKD undergoing dialysis and receiving ESAs to receive Dapro or ESA (NCT02879305; *N Engl J Med.* 2021;385:2325–2335), a trend toward a lower incidence of first occurrence of TEEs was observed with Dapro (185/1487 [12.4%]) compared with ESA (215/1477 [14.6%]). Here, we examine the occurrence of vascular access thrombosis (VAT), the most frequent type of TEE in the ASCEND-D study.

Methods: Adjudicated TEEs (including VAT) were a component of a prespecified principal secondary outcome. VAT was predefined as the absence of bruit or thrill and/or an inability to successfully initiate dialysis via the arteriovenous access after initial successful use. All suspected TEEs were adjudicated by the blinded Clinical Events Committee (CEC) according to predefined criteria. *Post hoc* analyses of time to first occurrence of VAT and recurrent events of VAT were performed.

Results: The CEC adjudicated 1088 potential TEEs, including VAT. First occurrence of adjudicated VAT occurred in 164/1487 (11.0%) and 201/1477 (13.6%) pts in the Dapro and ESA groups, respectively; hazard ratio 0.80 (95% CI: 0.65–0.98; *P*=0.015; **Figure**). Based on a recurrent events analysis of VAT using the negative binomial model, the rate ratio was 0.80 (95% CI: 0.63–1.01).

Conclusions: In the ASCEND-D study, there was a reduced incidence of VAT events with Dapro compared with ESAs.

Funding: Commercial Support - The study and this analysis were funded by GSK.

SARS-CoV-2 Testing During Routine Hemodialysis Care: A Nationwide Pragmatic Clinical Trial

Maria E. Montez-Rath, Meri Varkila, Xue Yu, Julie Parsonnet, Glenn Chertow, Geoffrey A. Block, Shuchi Anand. *Stanford University, Stanford, CA.*

Background: Patients receiving dialysis face relatively high risks from viral infections including SARS-CoV-2. Early detection could facilitate treatment, reduce transmission, and strengthen public health surveillance. We evaluated the acceptability of routine SARS-CoV-2 screening among asymptomatic patients in dialysis facilities.

Methods: We conducted a pragmatic, cluster randomized trial in 57 US hemodialysis facilities from Feb-July 2023 in partnership with US Renal Care and Ascend Clinical Laboratory (NCT05225298). We tested patient level acceptability of two strategies for offering SARS-CoV-2 rtPCR tests: static frequency every two weeks (arm 1) versus dynamic frequency based on county COVID-19 levels (arm 2). We used wastewater surveillance if available or else CDC case and hospitalization rates to determine frequency of testing in the dynamic arm: weekly, biweekly or every four weeks for high, medium or low community levels, respectively). We randomized facilities by county and offered testing for three months.

Results: 2389 patients participated and 12,553 tests were offered (Table). A median of 6 versus 4 tests were offered per patient at static versus dynamic facilities. Test acceptability and positivity rates were 8.0% vs 7.7% (p=0.45), and 2.0% vs. 1.9% (p=0.56), at static versus dynamic facilities.

Conclusions: In this national trial integrating routine SARS-CoV-2 test offer in dialysis care in which a diverse group of patients participated, we found test acceptability was poor and did not vary by testing strategy. A dynamic testing strategy anchored to community transmission resulted in fewer tests offers per patient. Positivity rates among those tested indicate continued risk for transmission even during low COVID-19 incidence.

Real-World Effectiveness of Hemodialysis Modalities

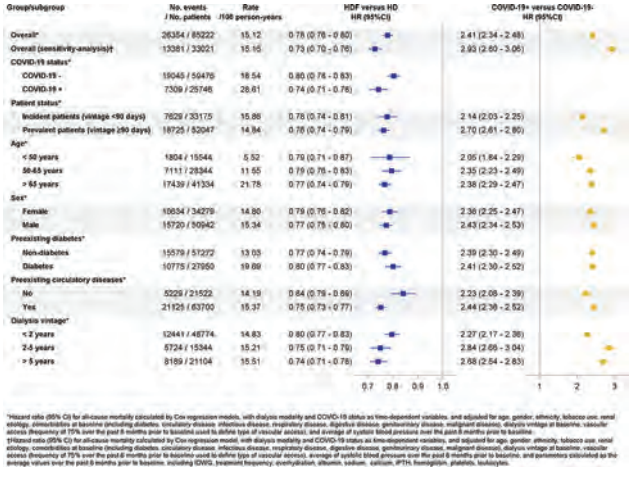
Yan Zhang,[1] Anke Winter,[1] Paola Carioni,[2] Belen Alejos,[1] Len A. Usvyat,[3] Franklin W. Maddux.[4] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care AG & Co KGaA, Milan, Italy; [3]Fresenius Medical Care Holdings Inc, Waltham, MA; [4]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany.*

Background: Results from the CONVINCE clinical trial suggest a 23% mortality risk reduction among patients receiving hemodiafiltration (HDF). We assessed the real-world effectiveness of HD modality (HDF versus hemodialysis (HD)) in a large, unselected patient population treated prior to and during pandemic years.

Methods: We included EuCliD data from 85,222 adult HD patients who were treated in EMEA NephroCare Clinics between 2019 and 2022 in the analyses. Cox proportional hazard models with HD modality and COVID-19 status as time-varying covariates and adjusted for multiple confounders were used to estimate all-cause mortality. Subgroup analyses were performed for age, patient status (incident/prevalent), COVID-19 status, diabetes, circulatory disease, and dialysis vintage.

Results: The mean age of the population was 63.2 years and 60% were male. During the median follow-up of 22.6 months, a documented COVID-19 infection was associated with an overall 2.4-fold increased all-cause mortality risk. Compared with HD patients, those treated with HDF had an adjusted hazard ratio for all-cause mortality of 0.78 (95% CI, 0.76-0.80). The pattern of a beneficial effect of HDF was consistently observed among all subgroups. Patients with a documented COVID-19 infection and those with a history of circulatory disease had a slightly more reduced effect estimate in subgroup analyses (Figure 1).

Conclusions: Our results suggest that hemodiafiltration has a beneficial effect on all-cause mortality in a large, unselected patient population and across patient subgroups that were treated in real-world settings. Our observational study complements evidence generated by the CONVINCE trial and adds to the growing body of real-world evidence on hemodiafiltration.



TH-PO1134

Patient-Reported Health Status of Adults with Kidney Failure Receiving Hemodiafiltration vs. Hemodialysis: Results from the CONVINCE Randomized Controlled Clinical Trial

Matthias Rose,[1] Felix Fischer,[1] Gregor Liegl,[1] Giovanni Strippoli,[2] Carinna Hockham,[3] Robin W. Vernooij,[4] Claudia M. Barth,[9] Bernard J. Canaud,[5] Adrian Covic,[12] Krister Cromm,[6] Andrew Davenport,[7] Kathrin I. Fischer,[1] Jorgen B. Hegbrant,[10] Hanna Jaha,[1] Anna Schappert,[1] Marietta Török,[8] Michiel L. Bots,[4] Peter J. Blankestijn.[11] For the CONVINCE Scientific Committee and Investigators. *[1]Psychosomatic Medicine, Center for Internal Medicine and Dermatology, Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [3]The George Institute for Global Health, School of Public Health, Imperial College London, London, United Kingdom; [4]Universiteit Utrecht, Utrecht, Netherlands; [5]MTX Consulting, Montpellier, France; [6]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [7]University College London, London, United Kingdom; [8]Diaverum AB, Malmo, Sweden; [9]B. Braun Avitum AG, Melsungen, Germany; [10]JBA Medical AB, Bjarred, Sweden; [11]Nephrology, University Medical Center Utrecht, Utrecht, Netherlands; [12]University of Medicine "Grigore T. Popa", Bucharest, Romania.*

Background: The CONVINCE trial showed a significant survival benefit for patients receiving high-dose hemodiafiltration as compared with conventional high-flux hemodialysis (N Engl J Med 2023; 389:700-709). A further objective was to compare the patient-reported health status between both interventions.

Methods: The CONVINCE Trial is multi-center, prospective randomized, open label, controlled trial, comparing benefits and safety of high-dose hemodiafiltration (HDF) versus high-flux hemodialysis (HD). The perceived health status was assessed in eight domains (physical function, cognitive function, fatigue, sleep disturbance, depression, anxiety, pain interference, social participation) using instruments from the Patient-Reported Outcome Measurement Information System PROMIS® before randomization and every three-month after over three years. The main analyses compared the mean change from baseline using an omnibus test for all eight domains, and a Linear Mixed Model to identify group x time interaction effects for specific domains.

Results: 1,360 patients have been enrolled, 677 receiving hemodialysis and 683 hemodiafiltration, with a median observation time of 30 month. For 84% of all treated patients PRO assessments could be analyzed (10,681 questionnaires). On average patients described statistically significant health deteriorations in all domains, with most pronounced declines in physical function scores. *Potential group differences between HDF vs HD will be disclosed at the ASN Congress.*

Conclusions: As of today, the CONVINCE trial has applied the most comprehensive assessment of PROs within a large RCT comparing HDF with HD, deepening the

understanding of the determining factors of perceived health of patients receiving renal replacement therapies. *The relevance of potential group differences will be discussed at the conference.*

TH-PO1135

Short- and Long-Term Effectiveness of Existing Insomnia Therapies for Patients Undergoing Hemodialysis (SLEEP-HD)

Rajnish Mehrotra,[1] Daniel Cukor,[2] Susan M. Mccurry,[3] Tessa Rue,[3] Maria-Eleni Roumelioti,[4] Patrick J. Heagerty,[3] Mark L. Unruh.[4] *[1]Medicine, University of Washington, Seattle, WA; [2]Rogosin Institute, New York, NY; [3]University of Washington, Seattle, WA; [4]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Nearly 50% of patients undergoing in-center hemodialysis report chronic insomnia, yet efficacy and safety of treatments is not known. This trial tested the comparative effectiveness of cognitive behavioral therapy for insomnia (CBT-I), trazodone, and placebo for insomnia in this population.

Methods: We undertook a randomized, multicenter, double-blinded, placebo-controlled trial in 26 dialysis units. Patients undergoing in-center hemodialysis with insomnia severity index (ISI) score ≥ 10 and sleep disturbances on ≥ 3 nights/week for ≥ 3 months were randomized 1:1:1 to 6-week treatment with telehealth CBT-I or trazodone or placebo. The primary outcome was the ISI score at 7- and 25-weeks.

Results: 923 patients were pre-screened, 411 had insomnia, and 126 were randomized to CBT-I (n=43), trazodone (n=42), or placebo (n=41). The ISI scores decreased in each group: CBT-I (baseline mean ± SD, 16.1 ± 4.8; 7-weeks, 12.3 ± 6.0), trazodone (baseline mean ± SD, 17.2 ± 5.4; 7-weeks, 12.5 ± 6.2), and placebo (baseline mean ± SD, 15.2 ± 4.4; 7-weeks 12.5 ± 5.3) and there was no significant difference in the average 7-week scores across groups. There was no meaningful difference in ISI scores at 25-weeks. There was no significant difference in other patient-reported outcomes at any time point, or use of sleeping aids, or with actigraphy. Serious adverse events, particularly cardiovascular hospitalizations, were more frequent with trazodone (Relative risk: trazodone vs. CBT-I, 12.2 (1.83, 519.2); trazodone vs. placebo, 3.1 (0.97-13.22)).

Conclusions: In patients undergoing in-center hemodialysis with chronic insomnia, there was no meaningful difference in the short- or long-term effectiveness of CBT-I or trazodone compared with placebo. Participants receiving trazodone had higher incidence of serious adverse events.

Peer Mentorship to Reduce Hospitalizations Among Patients Receiving Maintenance Hemodialysis: Results of the PEER-HD Trial

Ladan Golestaneh,[1] Michal L. Melamed,[1] Ryung S. Kim,[2] Kerri L. Cavanaugh.[3] *[1]Medicine, Albert Einstein College of Medicine, Bronx, NY; [2]Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY; [3]Medicine, Vanderbilt University Medical Center, Nashville, TN.*

Background: Hospitalizations contribute to up to 40% of the cost of care among patients receiving maintenance dialysis. PEER-HD is a pragmatic trial to test the impact on ED visit and hospitalization rates of a peer mentor led intervention in patients receiving hemodialysis.

Methods: This is a multi-center randomized controlled trial of 194 patient-participants (134 in Bronx NY and 60 in Nashville TN). Fourteen mentor-participants were recruited and trained. Patient-participants, identified as having high risk of hospitalization, were then recruited from affiliated dialysis facilities and those assigned to intervention (n=99) were matched to mentors. Mentors placed weekly telephone calls to assigned mentees over 3 months, after which patient-participants were observed for up to 15 months. The number of per patient-participant composite events during follow-up was recorded (median 12 months, range 2-18 months). The comparison of primary outcome between the intervention and usual care groups was made using Poisson regression with log of follow-up time as offset. Because there was significant interaction by study site we stratified the analyses.

Results: The mean age was 51.7 years, 51.5% were female, 56.2 % self-identified as Black and 39.2% self-identified as Hispanic. Baseline characteristics did not differ between randomized groups. The rates of ED visits and hospitalizations were 0.17 per patient-month in intervention group and 0.20 per patient-month in usual care group (incident rate ratio (IRR)=0.86; CI 0.70-1.06, p=0.15). Among the 134 patient participants in Bronx, NY there was a significantly lower rate of outcome in those assigned to intervention as compared to usual care (IRR= 0.70; CI 0.54-0.90; p=0.007). Among the 60 patients from Nashville, TN the difference in primary outcome was not significantly different (IRR= 1.25; CI 0.89-1.76, p=0.20). Post-hoc analysis showed that removal of 1 medically complex outlier made significant the overall effect of the intervention on outcome (IRR=0.85; CI 0.86-0.96, p=0.02).

Conclusions: Peer mentorship was not effective overall in reducing rate of hospitalization and ED visits, but was effective in Bronx NY. The protective effect of peer mentorship may be population specific, affected by area practice patterns or related to differences in mentoring activities.

Association of CKD-Associated Pruritus (CKDaP) with More Sleep Disorders, Increased Pain, and Worse Fatigue in US Hemodialysis Patients

Tejas Desai,[1] Rachel A. Lasky,[2] Kunal Malhotra,[3] Hans-Juergen Arens,[2] Juliana H. Oliveira,[1] Michael S. Anger.[2] *[1]Vifor Pharma Management Ltd, Glattbrugg, Switzerland; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]University of Missouri System, Columbia, MO.*

Background: Patients & their advocates emphasize symptom-based management for those afflicted with ESKD. There is an active call-to-action for Nephrology healthcare providers (NHCPs) to provide a holistic treatment plan: one that equally prioritizes symptom-based & biochemically-focused care. Three symptoms ESKD patients experience are sleep disorders, pain, & fatigue. These components are part of a cluster of symptoms known as SPADE in the Nephrology literature. This study investigates the association of CKDaP, an under– recognized & reported symptom, with these components.

Methods: A retrospective analysis of 81310 difelikefalin-naïve, >30-day hemodialysis vintaged in-center patients were stratified into the 5 validated groups of CKDaP burden descriptors in question 20 of the KDQOL-36 instrument. The burden of sleep disorder, pain, & fatigue were independently measured using questions 6, 8, & 25 of the KDQOL-36, respectively. Scores were re-coded from 0 (highest burden) to 100 based on the Rand Corporation's survey scoring instructions. ANOVA & logistic regression were used across pruritic levels. Mean (SD) are reported.

Results: Nearly 58% of patients experienced moderate or greater pruritic burden. Those patients with a greater CKDaP burden were statistically likely to have worse sleep, fatigue, & pain, both independently and in aggregate (table).

Conclusions: This data shows a strong association of CKDaP with 1) sleep disorders, 2) pain, & 3) fatigue. Patients afflicted with CKDaP endure a greater individual & aggregate symptom burden than those without. NHCPs who detect CKDaP & quantify its burden can potentially identify patients experiencing a) numerically higher-than-expected & b) more severe co-morbidities.

TH-PO1139

The Association Between Pruritus Severity and Mental Health-Related Quality of Life in over 80,000 Hemodialysis Patients

Linda Ficociello,[1] Tejas Desai,[2] Juliana H. Oliveira,[2] Hans-Juergen Arens,[1] Rachel A. Lasky,[2] Michael S. Anger.[1] *[1]Fresenius Medical Care Holdings Inc, Waltham, MA; [2]Vifor Pharma Management Ltd, Glattbrugg, Switzerland.*

Background: Chronic kidney disease associated pruritus is common in hemodialysis (HD) patients and can impact quality of life (QoL). The Kidney Disease Quality of Life 36-Item Short Form Health Survey (KDQOL-36) captures patient reported health-related QoL and symptoms including pruritus (q 20) and mental health-related factors, such as depression (q 11) and anxiety (q 9). Another tool, Patient Health Questionnaire-2 (PHQ2), measures depressive symptoms. The goal of this cross-sectional, retrospective database analysis was to evaluate the association of depression and anxiety scores with varying levels of pruritus.

Methods: Fresenius Kidney Care, adult, in-center HD patients with SF-36 measured between 1/1/21 and 2/28/23 are eligible. Patients answering that they are burdened by at least "moderate" pruritus were included in the analysis. A random sample of patients from the "not at all" and "somewhat" bothered respondents was selected. This stratified sampling technique was used to guarantee patients from each itch severity group will be adequately represented in the study population. ANOVA and logistic regression were used to test the mean scores (0=highest burden to 100=lowest burden) or odds ratios across itch levels. PHQ2 scores > 3 have been a screening tool for depression and were used to dichotomize scores into depression present or absent.

Results: 81,310 patients had completed SF-36, of which 77,978 (96%) also had PHQ2 completed within 30 days. Burden of anxiety ($p<0.0001$) and depression ($p<0.0001$) symptoms was more likely as itch intensity increased. Mean scores for anxiety and depression differed by pruritis severity. Next, using PHQ2 scores of > 3 to define depression, we found a stepwise increased risk of depression with each increase in pruritus intensity score (Figure 1). Patients who were extremely bothered by pruritus had 6 times the odds of having depression when compared to those patients "not at all bothered" by pruritus ($p<0.001$).

Conclusions: These data have shown a strong association of pruritus with depression and anxiety.

Funding: Commercial Support - CSL Vifor

Strategies for the Management of Atrial Fibrillation in PatiEnts Receiving Dialysis (SAFE-D)

Ziv Harel.[1,2] SAFE-D Investigators. *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada*.

Background: Atrial fibrillation (AF) is common in patients receiving maintenance dialysis. The role of oral anticoagulation (OAC) in this population is uncertain as dialysis recipients were excluded from landmark randomized control trials (RCTs).

Methods: Objective: To investigate the feasibility of conducting a full-scale RCT to assess the efficacy and safety of OAC in dialysis recipients with AF. **Design, setting, and participants:** We conducted a parallel-group, open-label allocation- concealed pilot RCT from December 2019 to December 2022 at 28 centres in Canada and Australia (ClinicalTrials.gov Identifier: NCT03987711). We included adults (≥18 y) undergoing maintenance dialysis with a history of non-valvular AF who met CHADS-65 criteria (i.e. age ≥ 65 y or the presence of at least one stroke risk factor). Exclusion criteria included contraindications to warfarin or apixaban, the need for anticoagulation for conditions other than AF and lack of clinician equipoise. **Interventions:** Dialysis recipients were randomized 1:1:1, stratified by centre, to receive dose-adjusted warfarin (targeting an INR of 2-3), apixaban, or no OAC. Follow-up was 26 weeks. **Outcomes:** We identified two thresholds for feasibility: recruitment of the target population within 24 months and retention of ≥ 80% of participants in their allocated arm at the end of follow-up. Principal secondary outcomes were ischemic stroke or systemic embolism, and bleeding (defined by International Society of Thrombosis and Hemostasis criteria).

Results: We screened 892 patients and enrolled 151(mean age 71.6 ± 10 y; 25% women; $CHADS_2$-VASc score 4 (IQR 3-5); prior stroke, 13%, prior major bleeding, 9%) who were allocated to apixaban (n =51), warfarin (n=52) or no OAC (n=48). We completed recruitment in 30 months (allowing for pauses related to the pandemic) and 83% of participants completed follow-up in their allocated treatment arm. Stroke occurred in 2 participants (1 apixaban, 1 no OAC), and 27 participants had at least one bleeding event (12 warfarin, 8 apixaban, 7 no OAC) of which 8 were major (4 warfarin, 2 apixaban, 2 no OAC). Death occurred in 15 participants (9 warfarin, 2 apixaban, 4 no OAC). Time in the therapeutic range for warfarin users was 58% (IQR 47%-70%).

Conclusions: This pilot RCT supports the feasibility of conducting a definitive RCT to inform the effect of OAC on clinical outcomes in dialysis recipients with AF.

The FAGOTTO Trial: Randomized Controlled Trial for Impact on Renal Hemodynamics of the SGLT2 Inhibitor Canagliflozin in Diabetic Kidney Disease

Nobuhiro Nishibori,[1] Sawako Kato,[1] Yosuke Saka,[3] Toshihiro Mizukoshi,[4] Tomohiko Naruse,[3] Hirotake Kasuga,[4] Takashi Miyata,[5] Masahiko Ando,[2] Yachiyo Kuwatsuka,[2] Hiroshi Arima,[5] Shoichi Maruyama.[1] *[1]Nephrology, Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Center for Advanced Medicine, Nagoya Daigaku Igakubu Fuzoku Byoin, Nagoya, Japan; [3]Kasugai Shimin Byoin, Kasugai, Japan; [4]Kaikoukai, Nagoya, Japan; [5]Endocrinology and Diabetes, Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan*.

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have a potential to maintain renal function in the long-term despite of a dip on glomerular filtration rate (GFR) slope shortly after administration. We evaluated change of renal hemodynamics during GFR dip in patients (pts) with type 2 diabetic kidney disease (DKD) with moderate renal dysfunction [30 ≤ estimated GFR (eGFR) ≤ 60 mL/min/1.73 m^2].

Methods: The FAGOTTO (jRCTs041200069) was a 12-week multicenter, open-label, randomized (1:1=canagliflozin : control), parallel-group trial. We directly measured GFR (mGFR) and effective renal plasma flow (eRPF) by the clearance of inulin and para-aminohippuric acid at baseline and 4 weeks after start of the trial. We also assessed glomerular filtration fraction (FF), renal blood flow (RBF) and renal vascular resistance (RVR). The primary endpoint was change in FF.

Results: A total 111 pts were allocated. Mean age was 71 yrs; 73% were male; mean GFR, albuminuria and HbA1c were 46.0 ml/min, 371 mg/gCr and 6.9 %, respectively. Canagliflozin significantly reduced mGFR by -4.9 ml/min (95% CI: -7.2 to -2.6, P =0.0008), eRPF by -18.5 ml/min (-33.7 to -3.3, P = 0.0093), and RBF by -25.6 ml/min (-52.3 to 1.06, P = 0.021) vs control, respectively. No changes were observed in FF and RVR between these two groups. **Figure** shows the direct values. eGFRs were estimated 54.3, 50.8 and 48.6 ml/min in pts treated with canagliflozin and 54.7, 54.7 and 52.0 in controls at baseline, 4 and 12 weeks in a linear mixed model, respectively. Canagliflozin reduced eGFR after 4-week treatment (P = 0.009) and also 12-week (P = 0.032) vs control using Tukey-Kramer to correct for multiplicity.

Conclusions: SGLT2 inhibition reduced GFR and RPF while remained the levels of FF and RVR in DKD pts with moderate renal dysfunction.

Funding: Commercial Support - Mitsubishi Tanabe Pharma Corporation Co., Ltd.

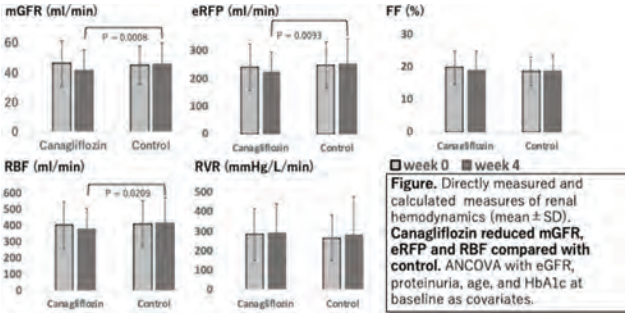

Figure. Directly measured and calculated measures of renal hemodynamics (mean ± SD). **Canagliflozin reduced mGFR, eRFP and RBF compared with control.** ANCOVA with eGFR, proteinuria, age, and HbA1c at baseline as covariates.

Background: In patients with chronic kidney disease (CKD) and type 2 diabetes (T2D), early reduction in urine albumin-to-creatinine ratio (UACR) is associated with improved kidney and cardiovascular outcomes. This post hoc mediation analysis quantified finerenone-induced kidney and cardiovascular (CV) risk reductions over a 4-year period mediated by a change in log UACR between baseline and month 4.

Methods: The analysis used pooled data from two phase 3 trials (NCT02540993 and NCT02545049) investigating the effect of finerenone vs placebo in patients with CKD and T2D. Separate causal mediation analyses were conducted for the composite kidney (kidney failure, sustained ≥57% decrease in estimated glomerular filtration rate from baseline, or kidney death) and CV (CV death, nonfatal myocardial infarction, nonfatal stroke, or hospitalization for heart failure) outcomes. The mediated effect of UACR reduction on the risk of cardiorenal outcomes was analyzed as a continuous variable (main finding) and as a dichotomous variable using the guideline-recommended 30% reduction threshold.

Results: Baseline median UACR was 514 mg/g (N=12,512). UACR reduction, analyzed as a continuous variable, mediated 83% and 36% of the treatment effect of finerenone on the kidney and CV outcomes, respectively (**Figure 1 C and D**). When UACR change was analyzed as a dichotomous variable, the proportions mediated were 62% and 25%, respectively (**Figure 1 A and B**).

Conclusions: In patients with CKD and T2D, early albuminuria reduction with finerenone mediated a large proportion of the treatment effect against CKD progression and a modest proportion of the effect against CV outcomes.

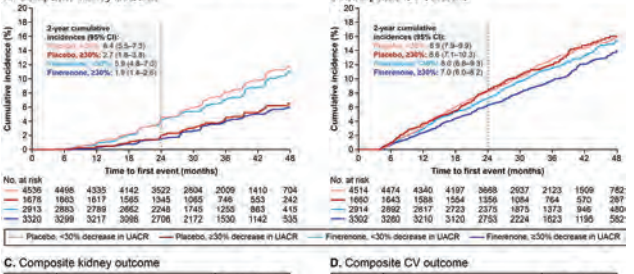
Figure 1. Cumulative incidences by treatment and relative reduction in UACR at 4 months and causal mediation analysis



C. Composite kidney outcome

Composite kidney outcome (n=12,400)	Effect	RMS[a] (95% CI)
	Independent of reduction in log UACR	1.02 (0.96–1.09)
	Mediated by reduction in log UACR	1.12 (1.10–1.15)
	Total effect	1.15 (1.07–1.22)
	Proportion mediated	0.83 (0.47–1.00)[b]

D. Composite CV outcome

Composite CV outcome (n=12,344)	Effect	RMS[a] (95% CI)
	Independent of reduction in log UACR	1.05 (1.00–1.16)
	Mediated by reduction in log UACR	1.04 (1.02–1.06)
	Total effect	1.12 (1.03–1.21)
	Proportion mediated	0.36 (0.09–0.63)[b]

Cumulative incidence calculated using an Aalen–Johansen estimator with all-cause death as a competing risk. Causal mediation analyses using change in log UACR (continuous variable) as the mediator. **Panel A** shows that an early change in UACR appeared to be a strong driver for the early separation of the incidence rate functions for the composite kidney outcome; in comparison, treatment group assignment produced a much smaller separation. **Panel B** shows that a separation of incidence rate functions for the composite CV outcome was not evident for the placebo group regardless of UACR change. However, CV event rates were separated as a function of UACR change in the finerenone group. **Panels C** and **D** show that the total effects of finerenone on the composite kidney and CV outcomes, respectively, were decomposed into effects independent of UACR reduction and effects mediated by reduction in log UACR. By comparing the relative magnitudes of the direct and indirect effects, the roles that UACR reduction played in achieving clinical benefits were determined.
[a]Estimates for RMS above 1 indicate greater mean event-free survival time; [b]proportion mediated values were calculated based on the estimates for the effect mediated by reduction in log UACR and the total effect or the corresponding logarithmically transformed RMS times.
CI, confidence interval; CV, cardiovascular; RMS, relative mean survival; UACR, urine albumin-to-creatinine ratio.

Background: Sodium-glucose cotransporter 2 (SGLT2) inhibitors reduce the urinary albumin-to-creatinine ratio (UACR) in patients with elevated albuminuria in the presence or absence of heart failure (HF) or type 2 diabetes mellitus (T2D). However, these effects have not yet been reported in the presence of both HF and T2D.

Methods: DAPPER is a multicenter, randomized, open-labeled, standard treatment-controlled trial that enrolled patients at 18 sites in Japan. Eligible participants with both HF and T2D were randomly assigned to a dapagliflozin or control (anti-diabetic drugs other than SGLT 2 inhibitors) with a 1:1 allocation. The primary outcome was the changes in UACR from baseline after a two-year observation, and the secondary endpoints were cardiovascular (CV) events and parameters related to HF.

Results: Between May 2017 and March 2020, 294 patients were randomly assigned to the dapagliflozin-group (n=146) or control-group (n=148). The mean age was 72.1 years and 29% were female. The mean HbA1c was 6.9%, mean NT-proBNP was 429.1 pg/mL, mean estimated GFR was 65.7 ml/min/1.73 m^2, and median UACR was 25.0 mg/g Cr in the dapagliflozin-group and 25.6 mg/g Cr in the control-group. In the dapagliflozin-group, when 122 patients completed the study, 107 (87.7%) had been taking 5 mg daily. The primary outcome did not differ between the dapagliflozin and control groups. Among the secondary endpoints, the mean decrease in left ventricular end-diastolic dimensions was greater in the dapagliflozin-group than in the control-group. The composite endpoint, defined as CV death or hospitalization for CV events, hospitalization for HF events, hospitalization for all causes, and an additional change in prescriptions for HF were also suppressed in the dapagliflozin-group.

Conclusions: Although dapagliflozin 5 mg daily, the major dose of the present study, did not reduce urinary albumin excretion in HF patients with T2D compared to the control, dapagliflozin decreased CV events and suppressed left ventricular remodeling.

Efficacy and Safety of Sotagliflozin in Patients with Type 1 Diabetes and CKD

Vikas Sridhar,[1] Ayodele Odutayo,[1] Satish K. Garg,[2] Thomas Danne,[3] Alessandro Doria,[4] Michael Mauer,[5] Michael J. Davies,[6] Phillip Banks,[6] Manon Girard,[6] David Cherney.[1] *[1]Nephrology, University Health Network, Toronto, ON, Canada; [2]Barbara Davis Center for Diabetes, University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Medizinische Hochschule Hannover, Hannover, Germany; [4]Joslin Diabetes Center, Boston, MA; [5]University of Minnesota Twin Cities, Minneapolis, MN; [6]Lexicon Pharmaceuticals Inc, The Woodlands, TX.*

Background: People with T1D, chronic kidney disease (CKD) and poor glycemic control are at high risk of kidney failure and cardiovascular events. Sodium-glucose cotransporter (SGLT) inhibitors improve glycemic control in adults with T1D but with an increased risk of diabetic ketoacidosis (DKA). This *post hoc* analysis evaluated the efficacy and safety of sotagliflozin (SOTA), a dual SGLT1 & 2 inhibitor, in patients with T1D and CKD.

Methods: Using patient-level data from inTandem 1 & 2, the effects of SOTA (200 or 400 mg daily) added to optimized insulin therapy on A1C, body weight (BW), systolic

blood pressure (SBP), eGFR, total insulin dose, adjudicated severe hypoglycemia (SH) and DKA were compared to placebo in a patient subgroup with T1D and CKD (eGFR <60 mL/min/1.73 m^2 and/or UACR ≥30 mg/g).

Results: In the 1575 patients, 237 (15%) had CKD. At baseline, patients with CKD were older, had longer T1D duration, lower eGFR, lower insulin pump use, higher total daily insulin dose, SBP, and UACR compared to the overall cohort. Relative to placebo, treatment with SOTA provided similar significant reductions in A1C, SBP and BW in the CKD and overall cohorts, but numerically smaller % reduction in total insulin dose at week 24 in the CKD cohort (Table 1). SOTA *vs.*placebo was associated with lower SH and higher DKA risk. However, the relative risk of SH and DKA appeared to be lower in the CKD *vs.* overall cohort over 52 weeks (Table 1). The expected acute eGFR decline followed by stabilization with SOTA was preserved in the CKD cohort.

Conclusions: In patients with T1D and CKD, treatment with SOTA had similar A1C and SBP lowering effects, and a lower relative risk of SH and DKA vs. the overall cohort.

The ALL STAR CKD Trial: Pleiotropic Effect of Atorvastatin Focused on Renoprotection in Patients with CKD

Eriko Yamamoto,[1] Sawako Kato,[1] Masahiko Ando,[2] Shoichi Maruyama,[1] Yoshinari Yasuda.[1] *[1]Nephrology, Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Nagoya Daigaku Igakubu Fuzoku Byoin, Nagoya, Japan.*

Background: Statins have been recognized for their pleiotropic effects which include anti-inflammation, antioxidant, improved endothelial function, stabilization of atherosclerotic plaques, and also reducing proteinuria. In this trial, we evaluated renoprotective effect of atorvastatin beyond lipid lowering in patients with chronic kidney disease (CKD) and hyperlipidemia.

Methods: The ALL STAR CKD (UMIN000006662) study was a 6-month multicenter, open-label, randomized (1:1= atorvastatin : ezetimibe), parallel-group trial of CKD patients with serum low-density lipoprotein cholesterol (LDL) ≧ 140 mg/dL (if patients with diabetes mellitus, LDL ≧ 120). The patients were allocated to receive once-daily atorvastatin 10 mg or ezetimibe 10mg: intestinal absorption of cholesterol inhibitor. We directly measured Glomerular Filtration Rate (mGFR) by the clearance of inulin at baseline and 6 months after start of the trial. We also assessed estimated GFR based by creatinine (eGFRcr) and cystatin C (eGFRcyst), and protein/albuminuria. The primary endpoint was the change in mGFR after 6 months of treatment in the atorvastatin group (Group A) and ezetimibe groups (Group E).

Results: A total 117 patients (men 53%, 56.7 years) were randomized. Mean eGFRcr, albuminuria and LDL were 54.3 ml/min, 178 mg/gCr and 150 mg/dL at the baseline, respectively. Serum LDL levels in Group A were significantly lower than those in Group E at six months after start of the trial (Group A vs Group E; 83.7 ± 25.1 vs 114.5 ± 19.0 mg/dL). When we compared the mean change from baseline to six months between the two groups by Wilcoxon rank-sum test, there were no significant differences in any parameters including mGFR (Group A vs Group E; 1.4 ± 11.2 vs -1.1 ± 18.9 ml/min: P = 0.09), eGFRcr (-6.7 ± 9.5 vs -6.1 ± 9.5 ml/min: P = 0.87), eGFRcyst (3.7 ± 8.1 vs 2.1 ± 6.4 ml/min: P = 0.37), proteinuria (-0.02 ± 0.36 vs 0.14 ± 0.65 g/gCr: P = 0.23) and albuminuria (124 ± 617 vs 244 ± 698 mg/gCr: P = 0.40).

Conclusions: The present trial did not demonstrate renoprotective effects of atorvastatin after 6-month treatment, as either reservation of GFR or anti- proteinuria. A longer-term observation might be needed to detect a renoprotective power of statins as a pleiotropic effect of atorvastatin in CKD patients.

A Clinical Decision Support Intervention Results in a Clinically Significant Decrease in Mean Systolic Blood Pressure in a Pragmatic Clinical Trial in a Primary Care Setting

Lipika Samal,[1,2] John L. Kilgallon,[1,5] Stuart R. Lipsitz,[1,2] Heather J. Baer,[1,2] Michael P. Gannon,[1,6] Ryan Dunk,[1] Weng Ian Chay,[1] Richard J. Fay,[1] Pamela Garabedian,[1] Edward Wu,[1,7] Joseph V. Bonventre,[4,2] Gearoid M. McMahon,[4,2] Sushrut S. Waikar,[3] Patricia Dykes.[1,2] *[1]Division of General Internal Medicine, Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Section of Nephrology, Boston University Chobanian & Avedisian School of Medicine, Boston, MA; [4]Division of Renal Medicine, Brigham and Women's Hospital Department of Medicine, Boston, MA; [5]Hackensack Meridian School of Medicine, Nutley, NJ; [6]Eastern Virginia Medical School, Norfolk, VA; [7]Alabama College of Osteopathic Medicine, Dothan, AL.*

Background: Patients with chronic kidney disease (CKD) and hypertension (HTN) are at high risk for kidney failure and cardiovascular morbidity and mortality. Although both CKD and uncontrolled HTN are not difficult to diagnose, both often go unrecognized by primary care physicians (PCPs).

Methods: We conducted a pragmatic, randomized controlled trial involving PCPs and their patients in an academic medical center. Individual PCPs were randomized to intervention or usual care. All adult patients with a visit to a PCP were eligible and those with evidence in the electronic health record of CKD and uncontrolled HTN were automatically enrolled. The intervention consisted of a clinical decision support (CDS) intervention that delivered anti-hypertensive treatment recommendations (renin-angiotensin-aldosterone system (RAAS) inhibitors or hydrochlorothiazide for those on maximal RAAS inhibition). The primary outcome was the change in mean systolic blood pressure (SBP) between baseline and 180 days compared between arms. A secondary outcome was orders placed for recommended anti-hypertensive medications.

Results: The study included 184 PCPs and 2026 patients. Patient mean age was 75.3 years; 60% were female, and 71% were White. 80% of patients had an SBP measurement at 180 days +/- 60 days. We observed a 2.9 mmHg greater reduction in SBP in patients in the CDS intervention arm compared to usual care (95% CI 1.27,4.53; p=0.005). PCPs also placed more orders for recommended anti-hypertensive medications in the intervention arm (Table 1; p<0.0001).

Conclusions: A CDS intervention resulted in a clinically significant decrease in mean systolic blood pressure in a pragmatic clinical trial in a primary care setting.

A Phase 3 Multicenter, Randomized, Double-Blind, Placebo-Controlled Study of Enarodustat for the Treatment of Renal Anemia in Chinese Non-Dialysis CKD Patients

Xueqing Yu,[1] Zhiming Ye,[1] Xinling Liang,[1] Yanning Zhang,[2] Weiping Hu,[3] Xiaonong Chen,[4] Tianjun Guan,[5] Hua Zhou,[6] Ping Fu,[7] Yunhua Liao,[8] Hui Xu,[9] Aicheng Yang,[10] Hongwen Zhao,[11] Lili Yang,[12] Yujie Sun,[12] Yongzhen Xiao.[12] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]General Hospital of Northern Theater Command, Shenyang, China; [3]The First Affiliated Hospital of Xiamen University, Xiamen, China; [4]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [5]Zhongshan Hospital Xiamen University, Xiamen, China; [6]Shengjing Hospital of China Medical University, Shenyang, China; [7]West China Hospital of Sichuan University, Chengdu, China; [8]The First Affiliated Hospital of Guangxi Medical University, Nanning, China; [9]Xiangya Hospital Central South University, Changsha, China; [10]Jiangmen Wuyi Traditional Chinese Medicine Hospital, Jiangmen, China; [11]Third Military Medical University Southwest Hospital Department of Nephrology, Chongqing, China; [12]Shenzhen Salubris Pharmaceuticals Co Ltd, Shenzhen, China.*

Background: Enarodustat (ENA) is a novel Hypoxia-inducible factor-prolyl hydroxylase inhibitor indicated for treating anemia in chronic kidney disease (CKD) patients. This phase 3 trial was conducted to establish the efficacy and safety of ENA in Chinese non-dialysis CKD (ND-CKD) patients.

Methods: This was a randomized, phase 3, double-blind, placebo-controlled, extended open-label, multicenter clinical study (NCT06016036). It consisted of a 4-week screening period, 8-week double-blind period (DBP), 16-week open-label period (OLP), and a 2-week safety follow-up period. Patients in the investigational drug group received once-daily ENA tablets at an initial dose of 4 mg/d for week1-5, then were adjusted in the range of 1/2/4/6/8 mg/d for every 4 weeks based on Hb levels and its changes.

The primary endpoint was the change in Hb levels from baseline (week1) averaged over week7–9. Secondary endpoints included Hb levels, its changes and proportion of the iron therapy, etc. Exploratory endpoints included iron parameters, etc.

Results: In total, 156 patients which had not received erythropoiesis-stimulating agents (ESA) treatment for ≥8 weeks were randomized in a 2:1 ratio to receive ENA (n=103) or placebo (PLA, n=53). In DBP, the change of Hb from baseline (mean±SD) averaged over week7–9 was 15.99±9.46g/L vs 0.14±8.08 g/L in ENA and PLA group (P<0.001). The mean Hb increase in the first 4 weeks was 11.82±9.56g/L vs 1.58±7.56g/L, the difference(LSM±SE) was 10.23 ±1.55 g/L (P<0.001). 85.3% vs 30% (P<0.001) of patients achieved a Hb level of ≥100g/L averaged over week7–9. In ENA group, the cumulative proportion of iron therapy decreased from 45.6% at baseline to 13.4% during the OLP, and the mean hepcidin levels decreased 57.7% (P<0.0001) from baseline at week9. Regarding the safety results, the incidences of adverse events (77.7% vs 79.2%) and adverse drug reactions (18.4% vs 15.1%) in ENA and PLA group were similar. There were no significant clinical changes in lipid parameters in ENA group.

Conclusions: Enarodustat was more effective in treating anemia in ESA-Naïve Chinese ND-CKD patients than placebo. Meanwhile, it had a similar safety profile with the placebo.

Abstract Withdrawn

TH-PO1149

Real-World Effectiveness of SGLT2 Inhibitors on the Progression of Kidney Disease in Non-Diabetic CKD Patients with and Without Albuminuria

Afif Nakhleh,[1,2] Sivan Gazit,[3] Adi Gross,[4] Adva Yarden,[4] Naim Shehadeh,[1,2] Muhammad Abdul-Ghani,[1,5] Cheli Melzer Cohen.[3] *[1]Maccabi Healthcare Services, Tel Aviv, Israel; [2]Bar-Ilan University The Azrieli Faculty of Medicine, Safed, Israel; [3]Maccabi Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv, Israel; [4]Medical Affairs, AstraZeneca, Kfar Saba, Israel; [5]Division of Diabetes, The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: In renal outcome trials, SGLT2 inhibition slows the progression of kidney injury in patients with & without type 2 diabetes (T2D). It is imperative to examine the renal effects of SGLT2 inhibition specifically among patients with chronic kidney disease (CKD) without T2D in a real-world setting.

Methods: We collected de-identified data on adult patients without diabetes who had an estimated glomerular filtration rate (eGFR) of 25-60 ml/min/1.73m^2 & initiated SGLT2 inhibitor (SGLT2i) dapagliflozin or empagliflozin between 9/2020-11/2022 in Maccabi Healthcare Services, a large Israeli health maintenance organization. We assessed the effect of SGLT2i on renal function, measured as the change in eGFR slope over time. The index date was defined as the date of the first dispensing of SGLT2i. Annual baseline slope was calculated by using all eGFR measurements within 2 years prior to index date (median of 7 measurements), while annual follow-up slope was calculated by using all evaluations during 90-900 days after index date (median of 5 measurements). For both periods, at least 180 days between first & last eGFR measurements were required. Paired t-test was used to compare differences between baseline & follow-up annual slopes.

Results: This analysis included 354 patients with CKD without T2D who received SGLT2i & were followed for a median of 527 days. The mean age was 72.8±11.8, 26% were women & 91% used renin-angiotensin system blockade. The mean eGFR was 45.4±9.5 ml/min/1.73m^2. 146 (41%) of participants had urinary albumin-to-creatinine ratio (UACR)<30mg/g, 81 (23%) had UACR of 30-300mg/g, 74 (21%) had UACR>300mg/g & 53 (15%) had no UACR evaluation within 1 year before index date. The slope of eGFR over time was -5.6±7.7 ml/min/1.73m^2 per year at baseline & it was improved to -1.7±6.8 ml/min/1.73m^2 per year after SGLT2i administration, (p<0.001). This effect was independent of UACR (Table 1).

Conclusions: In real-world study of patients with CKD without T2D, SGLT2 inhibition was associated with a slower rate of kidney function decline, regardless of baseline UACR levels.

Funding: Commercial Support - AstraZeneca

Background: Chronic kidney disease (CKD) increases the risk of developing cardiovascular disease (CVD) and cognitive impairment. Curcumin is a polyphenol that has been reported to improve vascular and cognitive function in middle-aged and older adults, however its effects on vascular and cognitive function in patients with CKD are unknown. We hypothesized that 12-month curcumin supplementation would improve vascular and cognitive function in patients with CKD.

Methods: 88 adults with CKD (stage 3B or 4) participated in a 12-month, randomized, double-blind, placebo-controlled, parallel-arms intervention to examine the effects of curcumin (Longvida, 2000 mg/day) on vascular and cognitive function. Our primary outcomes were endothelial function and aortic stiffness determined from brachial artery flow-mediated dilation (FMD) and carotid-femoral pulse wave velocity (cfPWV), respectively. Our secondary outcomes were endothelium- independent dilation via nitroglycerin mediated dilation and cognitive function assessed via the NIH Toolbox Cognition Battery.

Results: 75% of the participants were male, 56% had diabetes, and 15% had a history of CVD. The mean±SD age and eGFR were 66±8 years and 34.7±10.8 ml/min/1.73m2, respectively. The median (IQR) UACR was 81.9 mg/g (9.7-417.3). Following 12-months of curcumin supplementation, we observed no change in brachial artery FMD, nitroglycerin mediated dilation, or cfPWV (P>0.05; Table 1). Additionally, we observed no change in processing speed, executive function, memory, or language (P>0.05; Table 1). eGFR, UACR, hemoglobin A1c, and blood pressure were unchanged (P>0.05).

Conclusions: 12-month curcumin supplementation did not change vascular or cognitive function in patients with CKD.

Electronic Health Record-Based Population Health Management to Optimize Care in CKD: Kidney CHAMP Randomized Clinical Trial

Manisha Jhamb, Melanie R. Weltman, Susan M. Devaraj, Linda-Marie U. Lavenburg, Zhuoheng Han, Alaa A. Alghwiri, Gary Fischer, Bruce L. Rollman, Thomas D. Nolin, Jonathan Yabes. *University of Pittsburgh, Pittsburgh, PA.*

Background: Large gaps in clinical care in patients with chronic kidney disease (CKD) lead to poor outcomes. We tested the effectiveness of an electronic health record (EHR)-based population health management (PHM) intervention at reducing CKD progression and improving evidence-based care in high-risk CKD.

Methods: In a pragmatic cluster randomized clinical trial, we randomized 101 primary care practices to either intervention or usual care, and enrolled patients aged 18-85 years with estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2, with high risk of CKD progression and not seeing a nephrologist. Multifaceted intervention included nephrology e-consult, pharmacist-led medication management, and CKD education. Primary outcome was time to ≥40% reduction in eGFR or End Stage Kidney Disease.

Results: Among 1,596 patients with mean age 74±9 years, 58% were females, 8% were Black, and mean eGFR 36.8±7.9 ml/min/1.73m^2. Over a median follow-up of 17.4 months, there was no significant difference in rate of primary outcome between the two arms (adjusted hazards ratio 0.99, 95% CI 0.69, 1.42; P=0.94). Angiotensin converting enzyme inhibitor/Angiotensin receptor blocker (ACEi/ARB) exposure was more frequent in intervention arm compared to control (rate ratio 1.22, 95%CI 1.04 to 1.44, P=0.018). There was no difference in secondary outcomes of hypertension control and exposure to unsafe medications, or adverse events between the arms.

Conclusions: Among patients with moderate to high-risk CKD, a multi-faceted EHR-based PHM intervention resulted in more exposure days to ACEi/ARB but did not reduce risk of CKD progression or hypertension control versus usual care. Several COVID pandemic related factors likely contributed to null findings in our study.

Control of Secondary Hyperparathyroidism with Extended-Release Calcifediol Is Associated with Slower CKD Progression

Charles W. Bishop, Stephen A. Strugnell, Akhtar Ashfaq. *Renal Division, OPKO Health Inc, Miami, FL.*

Background: Insufficient levels of serum total 25-hydroxyvitamin D (25D) increase the risk of secondary hyperparathyroidism (SHPT) in patients with stage 3 or 4 chronic kidney disease (CKD). SHPT develops and advances in most CKD patients because 25D is not reliably raised with cholecalciferol or ergocalciferol. SHPT is associated with accelerated CKD progression and dialysis onset, but mitigation of disease progression by effective control of SHPT has not been previously examined.

Methods: Progressive changes in estimated glomerular filtration rate (eGFR) were examined post-hoc in 166 patients with vitamin D insufficiency, SHPT and stage 3-4 CKD during 1-year of treatment with extended-release calcifediol (ERC) in pivotal trials (Sprague 2016). ERC was administered daily at 30 mcg increasing, as needed, after 12 weeks to 60 mcg to achieve a targeted ≥30% reduction in iPTH. Measurements of eGFR were obtained at baseline (BL) and quarterly intervals, and 25D (DiaSorin), calcium (Ca), phosphorus (P) and plasma intact parathyroid hormone (iPTH; Roche Elecsys) at BL and monthly. Mean BL or quarterly iPTH levels of ≤100 pg/mL were considered "controlled" and, if maintained at 4 of these 5 assessments, "consistently controlled".

Results: ERC treatment increased mean (±SE) serum 25D from 20.1±0.4 ng/mL at BL to 77.8±2.0 at end of treatment (EOT; $p<0.001$) and decreased mean iPTH from 146.6±4.7 pg/mL at BL to 104.4±6.5 at EOT ($p<0.01$) without clinically meaningful changes in mean serum Ca or P. Decreases in mean iPTH were unaffected by BL eGFR. Average eGFR decline was 2.3±0.5 mL/min/1.73m^2 over the 1-year treatment period but differed significantly and proportionally with duration of iPTH control, being maximal (4.1±0.7) in subjects who never achieved control (n=44) and minimal (0.61±1.2) in subjects achieving consistent control (n=51; $p<0.05$). The number of subjects achieving an increase in eGFR by EOT rose in proportion to the duration of iPTH control achieved from 6 (no control) to 18 (consistent control).

Conclusions: A post-hoc analysis of pivotal clinical trial data with ERC indicates that early, sustained, effective treatment of SHPT is associated with mitigation of eGFR decline in patients with insufficient 25D and stage 3-4 CKD. Prospective studies with ERC are warranted to confirm these findings.

TH-PO1153

Heart Failure and Edema Events Associated with Sodium Zirconium Cyclosilicate vs. Patiromer Treatment

Nihar Desai,[1] Abisola Olopoenia,[2] Jennifer A. Kammerer,[3] Jeffrey J. Budden,[3] Alexandra C. Gordon,[2] Asa C. Tysseling.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Cerner Enviza LLC, North Kansas City, MO; [3]Vifor Pharma Management Ltd, Glattbrugg, Switzerland.*

Background: Sodium zirconium cyclosilicate (SZC) and patiromer (PAT) are potassium binders that differ by exchange ion, sodium, and calcium, respectively. There is limited data on whether using sodium exchange could impact the risks of hospitalizations for heart failure (HHF) or severe edema in patients with hyperkalemia. We assessed the occurrence rates of pre-specified major encounters potentially related to electrolyte-/fluid-related imbalances when stratified by new users of PAT or SZC.

Methods: Using Cerner Real World Data, we conducted a retrospective cohort study among patients who were newly initiated on SZC or PAT between June 1, 2018, and December 31, 2021. Adults (≥ 18 years) were followed from their first SZC or PAT prescription (index date) until the end of the 6-month follow up period. We analyzed the occurrence of pre-specified outcomes, discontinuation of or switch from index medication or death. Based on baseline demographic and clinical characteristics, 1 PAT initiator was propensity score matched with 2 SZC initiators. Primary outcomes were any HHF, primary HHF, major edema encounter (MEE), or death. Cox Proportional Hazard regression models were used to estimate the association between SZC or PAT use and each outcome in the overall population and subgroups with/without prior heart failure (HF).

Results: The final cohort included 9,929 PAT initiators matched to 19, 849 SZC initiators. Mean age was 66 years old; about 50% had a history of chronic kidney disease stages 3-5, and 34% a history of HF. Incidence rates (IR) and risks of all outcomes: HHF (any/primary), MEE, and death were significantly higher in the SZC cohort compared to the PAT cohort. These findings were consistent among subgroups with/without prior HF (Fig. 1).

Conclusions: In this real-world data, SZC use (vs. PAT) is associated with increased risk of pre-specified encounters potentially sodium-/fluid-related, including among patients with/without pre-existing HF.

Real-World Effectiveness of Finerenone in Chinese CKD Patients Without Type 2 Diabetes

Li Zhou, Wenge Li. *China-Japan Friendship Hospital, Beijing, China.*

Background: No evidence has been reported for using finerenone in non-diabetic chronic kidney disease (CKD), although it is proven effective and safe for patients with CKD and type 2 diabetes(T2D).

Methods: This real-world retrospective study included Chinese CKD patients without T2D between November 2022 and August 2023. Patients received standard CKD treatment plus finerenone at dose of 10 or 20 mg once daily. Urinary albumin to creatinine ratio (UACR), estimated glomerular filtration rate (eGFR), and serum potassium (sK^+) were examined at baseline, 1 month, and 3 months after treatment.

Results: Totally 16 patients were analyzed (mean age: 55.38±14.37 years; 12 [75.0%] males) (Table 1). UACR was remarkably reduced compared to baseline at 1 month post-treatment and further reduced at 3 months post-treatment, with a median reduction of 200.41 mg/g (IQR, 84.04-1057.10, P=0.028; percent change, 44.52% [IQR, 31.79%-65.42%]) (Figure 1a). No significant eGFR decline was observed through 3 months follow up(Figure 1b). sK^+ levels remained within the range of 3.5-5.5 mmol/L with only minor fluctuations compared to baseline (Figure 1c). No treatment discontinuation or hospitalization due to hyperkalemia occurred.

Conclusions: Finerenone showed good effectiveness and safety in CKD without T2D patients in 3 month follow up. It should be verified by Future large prospective studies.

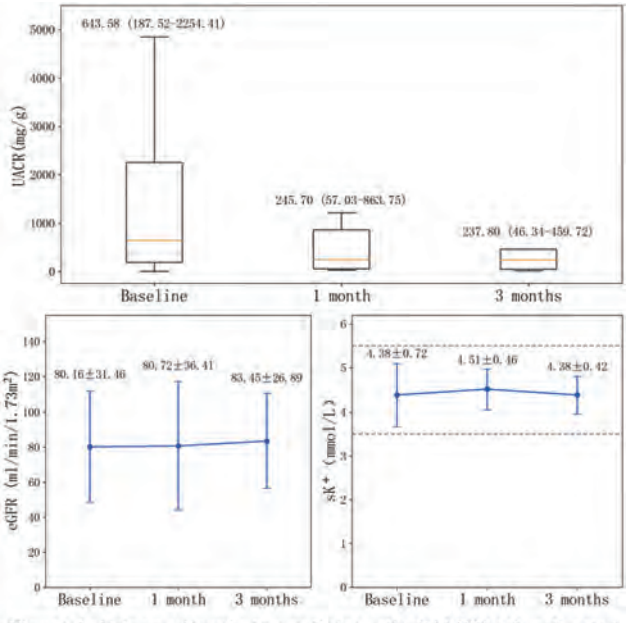

Figure 1. Urinary albumin to creatinine ratio (UACR) (a), estimated glomerular filtration rate (eGFR) (b), and serum potassium (sK^+) (c) levels at baseline, 1 month, and 3 months after finerenone treatment. Data are presented as mean ± standard deviation or median (interquartile range) according to normality. Dashed lines in Figure 1c present the range of 3.5-5.5 mmol/L.

Table 1. Baseline patient characteristics

Characteristics	Mean ± SD / n (%)

Hexasodium Fytate (SNF472) for Treatment of Calciphylaxis

Smeeta Sinha,[1,2] Sagar U. Nigwekar,[3,4] Lisa Gould,[5] Thomas E. Serena,[6] Sharon M. Moe,[7] George R. Aronoff,[8] Dinesh K. Chatoth,[9] Jeffrey L. Hymes,[9] Kevin Carroll,[10] Gabriela Alperovich Lehrer,[11] Laurence H. Keller,[12] Joan Perelló,[13,14] Alex Gold,[12,15] Glenn Chertow.[15] *[1]Renal Medicine, Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom; [2]The University of Manchester Faculty of Medical and Human Sciences, Manchester, United Kingdom; [3]Department of Medicine, Massachusetts General Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]South Shore Health, South Weymouth, MA; [6]SerenaGroup Research Foundation, Cambridge, MA; [7]Department of Medicine, Indiana University School of Medicine, Indianapolis, IN; [8]DaVita Inc, Denver, CO; [9]Fresenius Medical Care Holdings Inc, Waltham, MA; [10]KJC Statistics Ireland Limited, Dublin, Ireland; [11]CSL Vifor, Barcelona, Spain; [12]CSL Vifor, Wilmington, NC; [13]CSL Vifor, Palma de Mallorca, Spain; [14]University Institute of Health Sciences Research (IUNICS- IDISBA), Universitat de les Illes Balears, Palma de Mallorca, Spain; [15]Department of Medicine, Stanford University School of Medicine, Stanford, CA.*

Background: Calciphylaxis (or calcific uremic arteriolopathy, CUA) is a rare serious condition with no approved therapies characterized by severely painful ischemic skin lesions due to calcification in arterioles. CALCIPHYX was a phase 3, randomized, double-blind, placebo-controlled trial of hexasodium fytate, or SNF472, a selective inhibitor of vascular calcification, in patients on maintenance hemodialysis with calciphylaxis.

Methods: Adults with ≥1 ulcerated calciphylaxis lesion and Pain VAS score of ≥50/100 received SNF472 7 mg/kg or placebo IV during hemodialysis 3 times weekly for 12 weeks. Alternate primary efficacy outcomes were BWAT-CUA (an 8-item modification of the Bates-Jensen Wound Assessment Tool to assess relevant features of calciphylaxis) and Pain Visual Analog Scale (VAS). Safety outcomes included CUA wound-related complications.

Results: A total of 148 patients were screened, 71 were enrolled, and treatment was completed by 34 (91.9%) and 26 (76.5%) subjects in the SNF472 and placebo groups, respectively. At baseline, mean (SD) BWAT-CUA score was 19.8 (5.21), Pain VAS was 69.1 (27.9), and 69.0% of patients were treated with sodium thiosulfate. At Week 12, mean (SD) absolute change from baseline in BWAT-CUA was -5.3 (5.2) in the SNF472 group and -6.0 (6.2) in the placebo group, corresponding to a LS mean (SE) difference of 0.27 (1.33) (95% CI: -2.46, 3.00; p=0.88). Mean (SD) change from baseline in Pain VAS was -19.5 (26.9) in the SNF472 group and -32.2 (38.5) in the placebo group, corresponding to a LS mean (SE) difference of 11.49 (7.93) (95% CI: -4.80, 27.78; p=0.15). SNF472 was safe and well tolerated. Adverse events (AEs) leading to death were less frequent in patients randomized to SNF472: 1 (2.6%) vs. 6 (18.2%) in patients randomized to placebo. CUA wound-related AEs (11 [29.9%] vs. 16 [48.5%]) and wound-related infections (1 [2.6%] vs. 7 [21.2%]) were also less frequent in patients randomized to SNF472.

Conclusions: CALCIPHYX did not meet either alternate primary efficacy outcome. BWAT-CUA and Pain VAS improved similarly in both groups. There were numerically fewer AEs leading to death and CUA-wound related events and infections in patients treated with SNF472 compared to placebo. Detailed primary and post-hoc analyses will be presented.

Targeting Vascular Calcification in Calciphylaxis

Sagar U. Nigwekar. On behalf of VitK-CUA trial investigators. *Mass General Brigham Inc, Boston, MA.*

Background: Despite recent advances in the understanding of calcification inhibitors, there is no approved therapy for calciphylaxis-- a serious vascular calcification disorder that predominantly affects patients with end stage kidney disease. We sought to examine the link between pharmacotherapeutic strategies targeting vascular calcification (vitamin K, intravenous sodium thiosulfate, intralesional sodium thiosulfate, bisphosphonate, and calcimimetiic) and clinical outcomes in calciphylaxis.

Methods: We analysed data from phase 2, double-blind, placebo-controlled trial of phytonadione (vitamin K1) that enrolled adult hemodialysis patients with calciphylaxis (ClinicalTrials.gov #, NCT02278692). Eligible patients (n=26) underwent randomization to receive either oral phytonadione 10 mg (n=13) or placebo (n=13) thrice weekly for 12 weeks. Selection of other vascular calcification treatments was up to the clinician's discretion. We examined the associations between calcification treatments and clinical outcomes (pain intensity and skin lesion total surface area analysed as comparison between the end of trial and baseline). We explored whether the effect of phytonadione is influenced by the administration of co-treatments.

Results: Improvements in pain intensity and total lesion surface area were seen among 58% and 46% of patients, respectively. Phytonadione therapy led to improvements in pain intensity (92% phytonadione vs. 8% placebo, p<0.001) and total lesion surface area (69% phytonadione vs. 31% placebo, p=0.018) in higher number of patients compared with placebo. Intralesional sodium thiosulfate was administered to 39% of trial participants, 50% of trial participants were treated with cinacalcet, all received intravenous thiosulfate, and none received etelcalcetide or bisphosphonate. Intralesional sodium thiosulfate or cinacalcet by themselves were not associated with improvements in clinical outcomes. The effect of phytonadione was seen even among patients not treated with Intralesional sodium thiosulfate or cinacalcet.

Conclusions: Early data demonstrate that the effect of phytonadione is seen even in the absence of application of cinacalcet and intralesional sodium thiosulfate. Whether the effect differs according to the applicaiton of intravenous sodium thisulfate needs further investigation.

TH-PO1157

A Randomized, Controlled, Open-Label, Multicenter Study Evaluating the Efficacy and Safety of Lower Starting Dose Roxadustat for Anemia Treatment in Patients with CKD Not on Dialysis

Ping Li,[1] Guangyan Cai,[1] Xuefeng Sun,[1] Yiqing Wu,[2] Cuihua Huang,[2] Shuting Pan,[3] Xiangmei Chen.[1] *[1]Department of Nephrology, First Medical Center of Chinese PLA General Hospital, Nephrology Institute of the Chinese People's Liberation Army, National Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing Key Laboratory of Kidney Disease Research, Beijing, China; [2]Medical Affairs, FibroGen (China) Medical Technology Co., Ltd., Shanghai, China; [3]Clinical Biometrics, FibroGen (China) Medical Technology Co., Ltd., Shanghai, China.*

Background: Roxadustat is approved in China for chronic kidney disease (CKD)-associated anemia (CKD-anemia) treatment with and without dialysis. We assessed the non-inferiority of lower starting dose (LSD) roxadustat versus standard starting dose (SSD) for stage 3–5 CKD-anemia treatment without dialysis.

Methods: In this non-inferiority trial, patients were randomized (1:1) to a weight-based SSD (<60 kg: 70 mg three times per week [TIW]; ≥60 kg: 100 mg TIW) or LSD (<60 kg: 50 mg TIW; ≥60 kg: 70 mg TIW). Treatment was for 16 weeks (assessments every 2 weeks for 8 weeks, then every 4 weeks). The primary efficacy endpoint was the mean hemoglobin (Hb) change from baseline over weeks 12–16. Adverse events (AEs) were assessed during the treatment period and 4 weeks after completion.

Results: In total, 254 patients were randomized. The SSD (n=128) and LSD (n=126) groups had comparable baseline characteristics. The baseline Hb was 89.4 g/L (7.0) for LSD & 90.6g/L (6.7) for SSD. In the per protocol set (PPS) (n=226), the mean Hb change from baseline over 12–16 weeks was 21.6 g/L for LSD and 26.4 g/L for SSD (–4.78 g/L, 95% confidence interval [CI] –7.77 to –1.79 g/L [<–5 g/L non-inferiority margin]). In the PPS, 47.8% of the LSD patients achieved Hb 100–120 g/L over weeks 12–16 versus 47.7% for the SSD (odds ratio 1.158, 95% CI 0.671 to 1.996; P=0.60). The full analysis set (n=249) had similar results. The LSD group had significantly lower rates of change in Hb from baseline to weeks 4 (P=0.03), 8 (P=0.03), and 16 (P<0.01). There were 3 (2.4%) of the LSD & 2 (1.6%) of the SSD patients received rescue therapy. In the safety set (n=250), 68.0% of patients had treatment-emergent AEs (LSD 72.2%; SSD 63.7%). The proportions of treatment-emergent serious AEs (24.6% vs 10.5%) and drug-related AEs (4.0% vs 2.4%) were numerically higher with the LSD than the SSD.

Conclusions: Non-inferiority was not established for the LSD compared with the SSD in stage 3–5 CKD non-dialysis patients. The proportion of patients who achieved Hb 100–120 g/L over weeks 12–16 for both groups was similar; patients receiving the LSD had less Hb fluctuation. Both dosages were well tolerated, however, LSD did not show a better safety profile.

CER-001, an Engineered High-Density Lipoprotein, Shows Beneficial Pleiotropic Effects in Patients with Sepsis in RACERS: A Phase 2A Randomized Control Trial

Marco Fiorentino, Alessandra Stasi, Rossana Franzin, Loreto Gesualdo.
Nephrology Unit, Department of Precision and Regenerative Medicine and Ionian Area (DiMEPRE-J), Universita degli Studi di Bari Aldo Moro, Bari, Italy.

Background: The cytokine storm, an excessive immune response in sepsis, leads to acute kidney injury (AKI) and multi-organ failure. Our recent research highlighted the diverse properties of HDL, including LPS scavenging, anti-inflammatory effects, and preservation of endothelial integrity in an LPS-induced AKI swine model. Subsequently, we investigated the effects of CER-001, an apoA-I-containing engineered HDL, in a Phase 2a clinical trial.

Methods: We conducted an open-label, randomized, dose-ranging trial (RACERS study, N° EUDRACT 2020-004202-60) in 20 septic patients with intra-abdominal infection or urosepsis. Patients were randomized to receive standard of care (SOC; n=5) or SOC + CER-001 (5 mg/kg BID, 10 mg/kg BID, or 20 mg/kg BID; n=5 per group) on days 1, 2, 3, and 6. The primary outcomes were safety and efficacy in preventing AKI onset and/or progression, while secondary outcomes included changes in inflammatory and endothelial dysfunction markers.

Results: Patients were enrolled from the ICU and Nephrology Unit during the early phase of sepsis (median time from hospital admission: 2 days). CER-001 treatment was well tolerated, and no serious adverse events were attributed to its use. Rapid normalization of apoA-I levels with CER-001 was associated with significant and sustained LPS removal ($p<0.05$ on days 3, 6 and 9) and subsequent immunomodulation. CER-001 treatment led to rapid and significant decreases in pro-inflammatory cytokines (e.g., IL-6, IL-8, TNF-α, MCP-1), endothelial dysfunction markers (sVCAM, sICAM) and mortality biomarker (sTREM-1), resulting in improved clinical outcomes regardless of sepsis type or severity. CER-001-treated patients had a reduced risk of developing or progressing to severe AKI and, in a subset of critically ill patients, a shorter ICU stay and decreased need for organ support.

Conclusions: CER-001 replicates the beneficial pleiotropic effects of natural HDL by scavenging LPS, reducing inflammation, and protecting the endothelium. Therefore, CER-001 represents a promising therapeutic strategy for sepsis management, improving outcomes and mitigating the cytokine storm and associated organ damage often observed in our patients.

Results of a Randomized Placebo-Controlled Double-Blind Adaptive Phase 2 Study (AKITA) Evaluating RMC-035 for the Prevention of AKI in Patients Undergoing Cardiac Surgery

Alexander Zarbock,[1] Jay L. Koyner,[2] Andreas Boening,[3] Daniel Engelman,[4] Claudio Ronco,[5] Michael Reusch,[6] Tobias Agervald.[6] *[1]Universitatsklinikum Munster, Munster, Germany; [2]University of Chicago, Chicago, IL; [3]University Hospital Giessen, Giessen, Germany; [4]Baystate Medical Center, Springfield, MD; [5]International Renal Research Institute of Vicenza, Vicenza, Italy; [6]Guard Therapeutics, Sweden, Sweden*.

Background: Acute Kidney Injury (AKI) is a common and serious complication following cardiac surgery and is associated with multiple acute and long-term kidney-related adverse outcomes, such as renal replacement therapy, irreversible loss of kidney function, progression of preoperative chronic kidney disease (CKD) and transition to End Stage Kidney Disease (ESKD). RMC-035 is a recombinant, modified therapeutic protein, mimicking endogenous Alpha-1-Microglobulin, that harbors potent anti-oxidative and heme-binding capacity.

Methods: Global multi-center Phase 2 randomized double-blind adaptive design parallel group study in patients at high AKI risk undergoing open-chest coronary bypass and/or valve surgery with use of cardio-pulmonary bypass. Enrichment for high AKI risk was accomplished by incorporating mandatory AKI risk factors to the eligibility criteria. Patients with eGFR <30 mL/min were excluded from the study. 177 subjects were randomized 1:1 and treated with either RMC-035 or placebo. Study drug was administered up to 2 days after surgery, in total 5 IV infusions. The primary efficacy endpoint was AKI (KDIGO definition) within 72h after surgery. Important secondary endpoints included eGFR change from baseline up to Day 30/90 and MAKE (Major Adverse Kidney Events), a composite defined by death, any post-surgery dialysis or ≥25% eGFR decline from baseline on Day 30/90.

Results: Efficacy results on AKI, eGFR & MAKE and safety will be shared after availability of top-line results which are expected around September 20.

Conclusions: Conclusions will be shared after availability of top-line results, expected around September 20.
